What Does the Bot Between Fans and Artists Promise?

Conversational Bots × Always-On Agents × the Entertainment Business

An in-depth analysis of entertainment bots and always-on agents. It distinguishes promises that are kept within the conversation at hand from promises that remain after the conversation ends, and sets out the conditions of memory, authority, and official status needed to keep them. In a market where general-purpose AI alone can already deliver conversation and automation, it asks what an entertainment company can add.

Services That Offer Conversation and Services That Carry On Delegated Work

Even in the same chat window, users can expect different things. One person wants to know what time a concert starts; another wants to talk with a favorite character. Yet another wants someone to wait for a concert that has not been announced yet and then check whether it fits their schedule and budget. The first two requests can deliver their value within the current conversation. The third requires managing work that remains afterward.

The difference between existing bots and always-on agents begins here, with what promise the service takes on. Beyond how natural the answers sound, the heart of the comparison is whether the service can hold on to goals and conditions after the conversation ends and pick the work up again at the moment it is needed. In the entertainment business, three kinds of value have to be examined separately: the value of the conversation shared with a fan, the value of supporting what the fan actually does, and the value of carrying on the work of the company and its managers.

Picture the night after a concert. On the way home the last song is still circling in the fan's head. The fan opens their phone and leaves a short message: "I cried a lot listening to the last song tonight." A moment later a reply arrives. It is in the familiar voice they heard from the stage. It even remembers that a few days ago they said they loved that song.

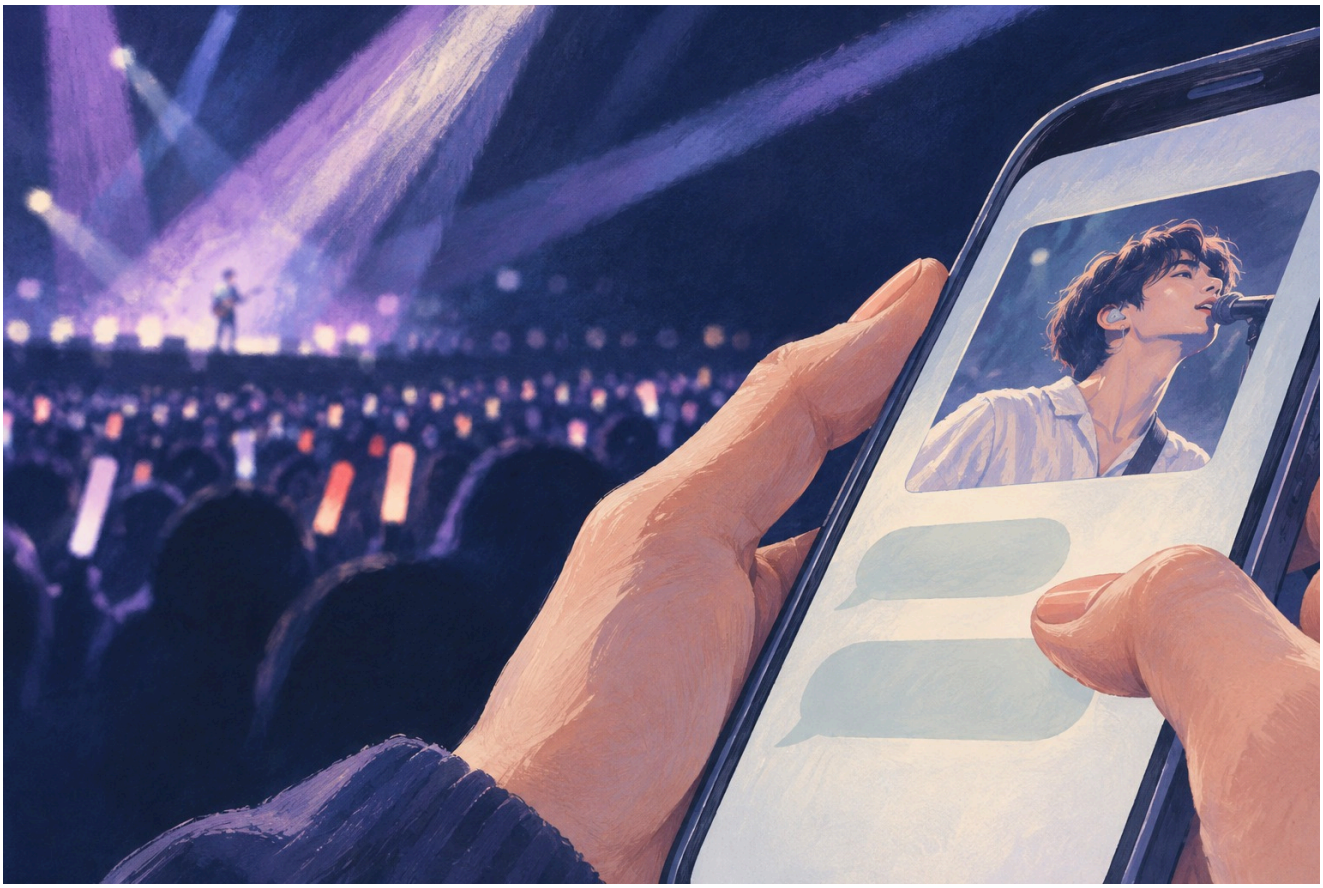

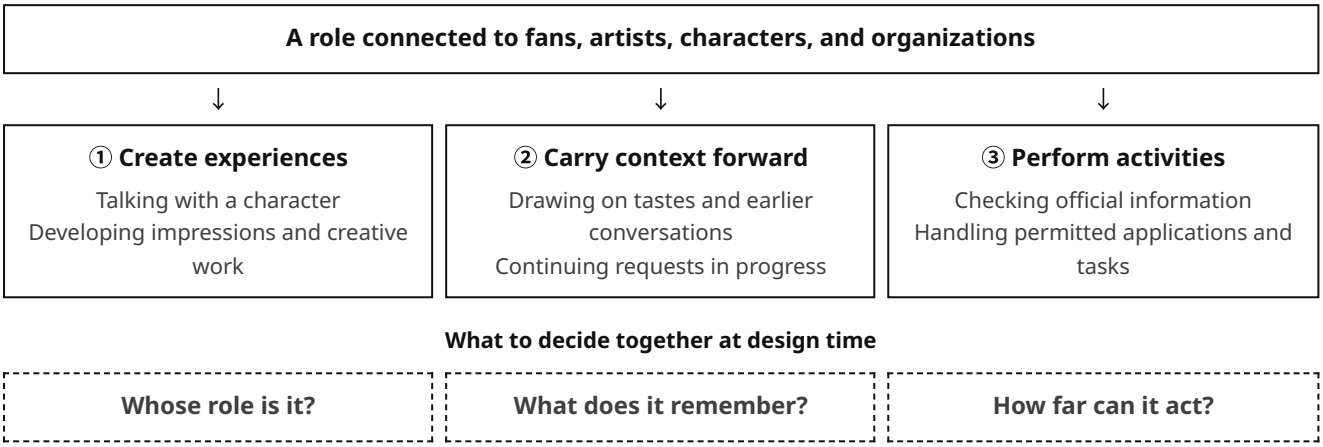

Figure 1. The stage in the venue and the screen in the hand: a fan meets the same artist in two different ways, through the concert and through messages

This scene is an imagined situation, made up to think about what bots make possible. A real artist may have read the message and replied, or an official bot connected to the artist may have responded. The sentences on the screen may look alike, but the relationship the fan experiences and the meaning of the reply are different. What the fan can expect changes depending on whose words they are, what the reply was based on, and who remembers the earlier conversation.

After enjoying that conversation, the fan might ask their own bot to look into the next concert dates. The personal bot checks the published schedule and compares it with the fan's own calendar, within the scope the fan has allowed. The company's official service explains the conditions for taking part, and the manager's work bot checks that the information confirmed internally has been reflected correctly. In a scene like this, several kinds of bots take on different jobs.

This report describes an entertainment bot as software that has a role connected to fans, artists, characters, or organizations, creates experiences through conversation and interaction, carries the necessary context forward, and performs permitted activities. This is the working definition used here. It does not mean every bot must have all of these functions. Some bots only offer conversation, some find information, and some actually carry out the work entrusted to them.

The three functions are not stages of development. Depending on each bot's purpose, some or several of them are combined.

Figure 2. Three functions for understanding entertainment bots: the functions needed are combined according to the role the bot takes on

Looking at the main official materials and market surveys as of November 11, 2026, these functions are being implemented in different forms across personal AI services, enterprise work platforms, underlying development technologies, and fan services. This report explains those differences and examines where the entertainment business stands, using the adoption and revenue structures that can be confirmed. A service's official announcement is evidence of its features and availability; it does not mean that its effect on users or its profitability has been independently verified.

Part I

How Fans and Artists Meet

Chapter 1. What Have Existing Bot Services Offered?

The term "existing bots" does not point precisely to a single product category. It can include a bot that shows a notice in response to a fixed question, an AI support bot that searches company materials to answer, a bot that offers conversation with a character, and a bot that processes orders or reservations. In this report, services that take a user's question or a specific request and provide answers and tasks are grouped as "conversation-centered bots" for the purpose of comparison. This does not mean all existing bots have the same functions.

Conversation-centered bots are useful for getting needed information quickly, producing an expression, or handling a defined task. For a bot that tells you the door time of a concert, accurate guidance matters; for a character bot, the consistency of the story and the pleasure of the conversation matter. For a bot that processes orders, what matters is that the transaction is completed correctly. Even when the same chat window is used, the value to be evaluated differs.

There are already cases where conversational bots look up external data or carry out real actions. Salesforce's official technical documentation also includes information lookup and command execution in the role of a conversational agent. So dividing things wholesale into "existing bots only talk and agents act" misses reality. Functions such as memory, tool use, and notifications can be built into many kinds of services.[1]

Fan communication platforms also need to be distinguished separately. DEARU presents bubble as a service for exchanging messages with real artists. A feature that delivers messages written by the artist and a feature in which AI generates new responses differ in who provides them and in what the experience means. A service like bubble should not be placed among bot services for comparison merely because it has a chat screen.[2]

This distinction also brings out the value that existing services hold. A fan may pay to hear news from the real artist, or may pay to create stories with a character or to find information conveniently. There is no basis for assuming that the agents that come later replace all of this value at once. The value that new functions add and the value that existing experiences must preserve have to be considered together.

Chapter 2. From Fan Letters to Messaging Apps

Someone who writes a fan letter hopes for more than the mail arriving. They want to convey what a favorite song meant to their day, or how long they waited to go to a concert. Sending a letter holds both the joy of expression and the hope that someone will read it.

The channels through which fans convey their feelings include letters and fan club boards, comments and live broadcasts, and messaging apps, all existing side by side. Public comments can become a place to share impressions with other fans, while a message screen calls to mind a private conversation. Fans enjoy the content and at the same time express what they felt and share interpretations with others.

The lasting sense of closeness and bond people feel toward figures in the media has been studied academically under the concept of the "parasocial relationship." The term alone does not allow us to judge that a fan's feelings are false or that they lack real-world relationships. A meta-analysis published in the Journal of Communication in 2020 synthesized 120 related studies and did not find a significant association between a deficit in social relationships and parasocial relationships. Although it is not a study of AI bots, it is evidence that fan attachment is hard to explain by loneliness alone.[3]

The way a service is used also plays a part in the closeness fans feel. A 2026 study related to bubble combined the researcher's 275 days of usage observation, observation of online fan communities, and interviews with six female K-pop fans in China. The researcher analyzed how a screen that looks like a one-to-one conversation, the subscription model, and the permission to reply together construct an intimate experience. As a qualitative study of a particular group it does not represent every fan's response, but it shows the need to look at message content and platform rules together.[4]

Here, the look of the screen and the actual mode of communication have to be understood separately. Even a screen that looks like a private chat can send the same message to many fans. In a public broadcast, one fan's question may be picked out and answered directly. Whether the screen is personal and whether the reply was written for an individual are different matters. Nor should research analyzing the intimacy of existing messaging services be read as evidence that those services answer with AI.

When bots come in, the possibility is added of generating responses tailored to the question and continuing earlier conversations. To the same degree, the need grows to explain who produced the response and how far the fan's words are passed on. Enabling fans to understand and choose their own experience is the basic condition of a new mode of communication.

Chapter 3. If There Were Someone Who Always Answered

Suppose a fan living overseas finds a concert announcement in the middle of the night. They wonder what time it is in their own time zone, whether a membership is required to apply, and which link is the official place to register. A bot can be the point of contact that answers such questions. It organizes within a conversation the information the fan would otherwise have had to hunt for across many screens.

Another fan may want to chat for a while with a favorite character rather than look for information. They might ask about a place in the story, or hear an event told again from a character's point of view. In this case the value of the answer lies somewhere other than accurate schedule guidance. A response true to the character, the fun of the story, and the wish to keep the conversation going become what matters.

In this way, entertainment bots have a function that creates experiences, a function that carries earlier context forward, and a function that performs requested activities. A single bot can have several functions, but being natural in conversation does not by itself mean it can handle outside tasks. Explaining where a venue is and purchasing a ticket require different connections and different authority.

The fact that an answer is always possible does not mean the artist is always with the fan. What increases here is the opportunity for interaction that can be offered through a bot. Operators have to make the nature of the conversation and the scope of what is offered clear. Fans, too, should be able to enjoy each for what it is, distinguishing the experience of receiving news from the real artist from the experience of talking with a bot.

Chapter 4. Can a Conversation with a Bot Be Content in Itself?

Imagine that after watching a mystery drama you could ask a character, "Why did you make that choice in that scene?" The character answers on the basis of the work's established setting, and the fan adds their own interpretation. Even people who watched the same work ask different questions, so each conversation can go in a different direction.

In September 2025, Kakao Entertainment announced on Berriz an AI persona service based on characters from the drama Tempest (북극성). According to the official description, it uses the scripts to reflect each character's way of speaking and personality, and is set up so that fans exchange questions and answers. The conversation partner is an AI based on a character in the work. It should not be understood as a service that reproduces an actor's real thoughts or private life.[5]

The way fans build experiences through conversation also appears in user research. A study published in 2026 by researchers at UC Davis analyzed 813 Reddit comments about using Character.ai. The researchers identified a variety of motives for use, including extending fan activity, role-play and story creation, emotional support, social needs, and enjoyment. This was not a survey of 813 people, and the unrepresentative nature of comments collected from a particular platform has to be kept in mind. It is not a result that shows the share of preferences among all fans or their willingness to pay.[6]

What this material lets us think about is the scope of fan participation. After enjoying a finished story, a fan can add their own questions, imagine other possibilities, and develop their interpretation through conversation. A bot can be the counterpart that responds to this creative process. A fan may want the experience of talking directly with the real artist, but quite apart from that, they may also enjoy a story they can take part in.

Suppose a fan creates a scene in which they travel with a character to a place in the story. That scene can be presented as a fictional story made by the fan and the bot together. Keeping it distinct from the original setting fixed by the creators allows the fan's imagination while protecting the consistency of the work. This is why a device is needed to distinguish whether the official setting is changing or whether the story was made only within the conversation.

In evaluating the quality of such services, we need to look not only at the number of conversations but at what fans made and enjoyed. A short conversation can yield a new interpretation, and a fan who does not get the answer they want may repeat the same question. Treating the conversation itself as content means that the fan's questions and choices make up the experience.

Part II

Agents That Carry the Work On After the Conversation Ends

Chapter 5. What Changes with the Words "Always On"?

Suppose a fan asks their bot: "When the next concert is announced, compare it with my schedule and let me know. This month I can only spend up to 200,000 won, including travel." Searching for concerts that are public now does not finish this request. The bot has to wait for news that has not come out yet, check what is announced later, and see whether the fan's conditions still hold at that point. What is needed is the ability to manage work that remains after the conversation ends.

Figure 3. A closed laptop and a new concert notice: the conversation is over, but the request that was entrusted remains, and news that arrives later sets it in motion again

"Always-on agent" is a term that describes this way of operating. In this report it is used to mean an agent that stays on standby and carries on the work entrusted to it. Specifically, it refers to software built to maintain the delegated goal and the necessary context, the permitted authority and the state of the task, to start or resume work when triggered by a set time or an external change, and to check the result and report it. It is not offered as a definition belonging to any single established international standard classification.

Here, the expression "always on" has three meanings that need to be told apart. Being able to connect and ask a question at any time is the service's availability. The earlier delegated task and its processing state remaining in place is persistence. Running in response to time or change even when the user does not speak to it again is the way execution is started. A service can be reachable 24 hours a day and still have no function for holding on to something to be done later.

Criterion	Typical makeup of a conversation-centered bot	Design focus of an always-on agent
The user's request	Answers the current question or handles a specific request.	Also takes on what is to be done in the future and the conditions for doing it.
Start of work	Starts when triggered by a question, a command, or an action on the screen.	Also starts on a set time, new information, or a business event.
State to be kept	Can store the conversation and the usage information the service needs.	Carries forward goals, deadlines, changed conditions, and unfinished tasks.
Tools and actions	Can use tools such as search, lookup, and ordering.	Coordinates tool use at several points in time, and waiting for and resuming after approval.
After the conversation	What happens after the conversation ends depends on how the service is set up.	Keeps managing the delegated task for as long as the execution environment is maintained.
Criterion for completion	Evaluates the answer, the conversation experience, and the result of the requested transaction.	Checks the result and also reports failed, stopped, and unfinished states.
Focus of operation	Manages response quality, service availability, and the quality of each individual task.	Manages omissions, duplicate runs, changed conditions, expired permissions, and cumulative cost as well.

Table 1. Comparison of conversation-centered bots and agents that take on work continuously

This comparison is not a product ranking that divides functions into exclusive tiers. Add continuous execution and state management to an existing bot and it can be run in an always-on way. Work that fixed rules already handle well can be left to existing automation. AI can be connected to the parts that require interpreting the meaning of several sources or choosing the next step according to the situation. The "bot" as a point of contact and "always-on execution" as a way of operating can be built together.

To understand an ordinary conversational bot, we first look at the relationship between question and answer. With an always-on agent, we have to look at what is maintained in the time between questions. Being able to answer "Is there any news?" each time it is asked, and being able to store the request "Let me know when there is news" and act on it later, are different functions. Salesforce's technical documentation likewise distinguishes conversational agents, which respond to a user's request, from proactive agents, which start in response to events, data changes, or configured conditions. This classification is a reference frame for understanding how things work; not every service uses the same terms.[1]

The word "always" is easily taken to mean that an AI model is thinking nonstop all day long. In practice, a system can be built to store what needs to be done and the conditions for doing it, and to perform the necessary computation when the time comes or a change arrives. OpenClaw's official documentation describes automation features that store a task schedule, run the agent when the time comes, and send the result to a connected conversation channel. Periodic checks and notifications from external services also serve as triggers. What persists is the system that manages execution requests and state; the model can be called at the moment it is needed.[7]

Chapter 6. Does a Delegated Task Continue After the Chat Window Closes?

Three questions are needed together here. First, how long do the previously delegated goal and its processing state last? Second, what time or event causes the next piece of work to start? Third, how far can the work that has started act? The three questions are independent of one another. A bot that remembers preferences for a long time may never start work on its own, and a bot that runs regularly may still have no authority to pay. Bundling the abilities to "remember," to "start first," and to "act on someone's behalf" into a single description inflates expectations.

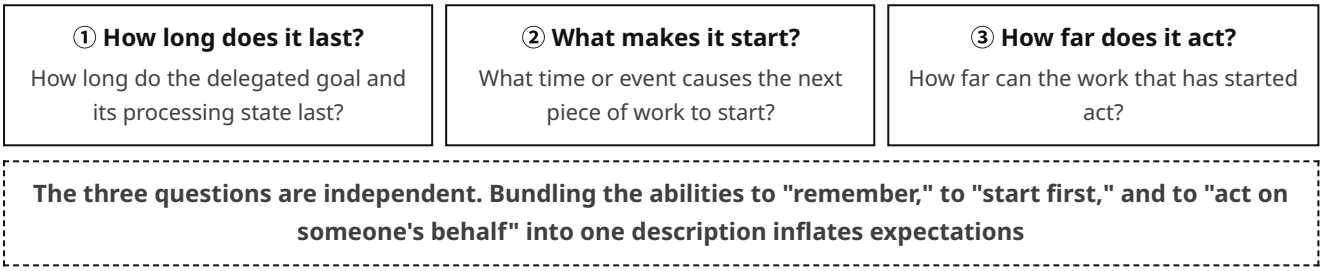

Figure 4. Three questions for examining an always-on agent

The difference from a simple notification can also be understood at this point. Sending the same sentence at a fixed time may be handled perfectly well by existing automation. Comparing the meaning of several announcements, building options that fit the fan's schedule and budget, and asking a person again about an ambiguous condition are where AI's interpretation and tool use can help. There is no reason to put an agent into every repetitive task. A setup in which existing programs handle fixed rules and AI is connected to the parts that need interpretation is also possible.

For work to continue after the chat window closes, the environment responsible for execution has to actually be kept running. The conditions differ between a service that runs in the cloud and one that runs on a personal PC. Work can stop when the network drops, when a connection's authorization expires, or when a usage limit is reached. So a function that reports status, such as "still checking," "access expired," "waiting for human approval," and "done," is also part of the experience. The user must be able to notice a state in which the service promised to keep working but is doing nothing.

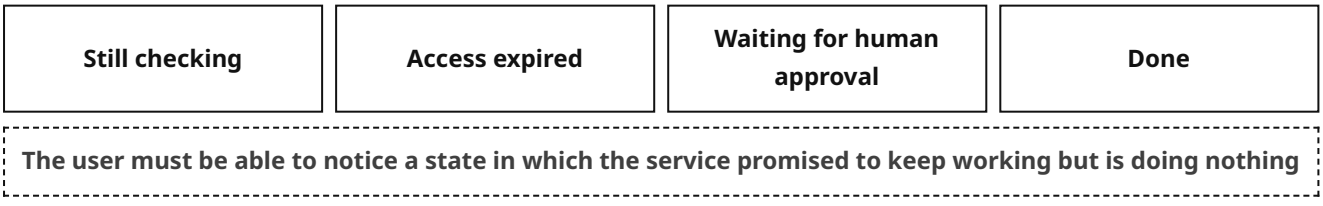

Figure 5. Examples of task states reported to the user

Being on standby also has to be distinguished from having permission to observe every activity. A request to check concert announcements does not create permission to read all of someone's private messages or to keep a microphone on. The service can be designed so that the fan understands and controls when and how often notifications arrive, what information is consulted, and how to stop it. In particular, when the budget or notification conditions the fan has set change, the new conditions must apply to the next run as well.

The bot account perspective examined later helps explain this way of operating. Even during the time when a person is not taking part in the conversation, it has to remain connected who delegated the task, which bot is carrying it out, and under what authority it ran. The account is the unit of management that links roles and records, and the model is the component that performs interpretation and generation within it. Even if the model or execution environment changes, it must be possible to confirm what is still being handled and where it stopped.[8][9]

In entertainment, the significance of the always-on agent lies in the fact that a fan's interest can carry beyond a one-off conversation into the next activity. Fans no longer have to repeat the same request, and companies and managers can pick up requests that are not yet finished. Its value can be confirmed not in how often it sends messages, but in whether it remembers the task it took on and handles it at the right time.

Chapter 7. How Do the Fan's and the Manager's Experiences Change?

Suppose a fan asks, "Let me know when this tour is announced. I only want to see weekend shows, and I want to keep the trip within 200,000 won including travel." A conversation-centered bot can find and explain the schedule that is currently public. An agent that takes on work continuously has to keep the request for news that is not yet public, and manage the official sources to check, the checking interval, and the conditions for ending. This scene is a design example to explain the difference, not a case of any particular company's current service.

When a new announcement goes up, the job may not end with simply sending a link. The agent has to check whether the announcement has been revised, compare it with the permitted schedule information, and sort out the options that fit the budget. If the fan changes the budget or the available dates, the change has to be reflected in the next run. If the same announcement has already been sent, duplicate alerts should be reduced, and if access to the calendar has expired, the agent should report that it could not complete the comparison.

Here, recommending and purchasing are distinct. The authority to find and report concerts that meet the conditions is different from the authority to carry out an actual payment. To support purchasing, it has to be decided whether the service in question permits the connection, what confirmation steps are needed, and how the result will be verified. The description "it finds the concerts you want" must not be stretched into the promise "it completes every booking automatically."

Persistence can be needed in a manager's work too. When a concert time changes, the agent can find the differences between existing announcements and the internal schedule, draft a correction, wait until the person in charge approves it, and then continue to the next step with the approved content. When the manager logs back in, it has to show what has been completed and what remains. The key is the ability to keep work from being dropped while information is changing.

This way of operating can connect to the conversation experience as well. Where the fan has agreed, the agent can prepare material for continuing a story they were making when a new episode is released, or gather their impressions after a concert into a record. But a bot reaching out first must not be described as the real artist thinking of the fan and contacting them personally. The agent's persistence and the artist's actual participation each have to be made visible.

Part III

The Fan's Bot, the Artist's Bot, the Company's Bot

Chapter 8. What Kind of Bot Does a Fan Want at Their Side?

For a fan who wants to go to the next concert, the information needed does not end with the concert date. Travel time and budget, who to go with, and even the next day's schedule have to be considered. The fan's personal bot can take on the role of organizing these conditions within the scope the fan allows and showing the options that can actually be chosen.

Figure 6. A light stick and a microphone, a headset and a schedule: the fan enjoys the concert, the artist creates, and the manager coordinates activities. The role a bot takes on depends on whom it is helping

For example, a bot that remembers the condition "this month I only want to spend this much, including travel" should help with choices that fit the budget. If no option meets the conditions, it should also be able to explain the choice of not taking part this time. The name "the fan's bot" carries the expectation that it puts the purpose the fan entrusted to it first.

Beyond preparing for concerts, there may be things fans want to make themselves: gathering scattered impressions into their own concert record, organizing their interpretation of a scene in a work, or polishing a piece of writing to share with other fans. The research on motives for use discussed earlier gives reason to consider these creative and playful aspects as well. The activities presented here are examples of use thought through on the basis of those findings, not the verified results of any particular service.[6]

An information helper on an official platform takes on yet another role. In August 2026, Weverse announced the beta of "Weverse AI," which finds notices, live content, and official merchandise information through conversation. Features such as providing original links and the relevant timestamps in live videos were introduced. It is a case of a helper that finds the information needed for fan activity, but its scope differs from a personal bot that manages the fan's life as a whole.[10]

Fans can therefore choose differently among a bot that organizes their own schedule, an official bot that checks announcements, and a character bot for enjoying stories. Even when one service offers several functions, it must be possible to know in which role it is currently answering. When it recommends merchandise, what matters is whose criteria it follows; when it helps with creative work, what matters is how much the fan can revise and decide.

When fans are not bundled into a single motive for use, the shape of services becomes more varied too. Some fans want convenience, some want the chance to express themselves, and even the same person wants different things in different situations. The starting point for designing a fan's bot is understanding which activities the fan wants to delegate and which they want to enjoy doing themselves.

Chapter 9. What Can an Artist's Bot Stand In For?

A bot that carries an artist's name can be made in many forms. It can explain published interviews and activity information, or converse as a character the artist has approved. It can be a digital figure that uses the artist's voice and appearance, or a separate mascot can introduce the artist's world.

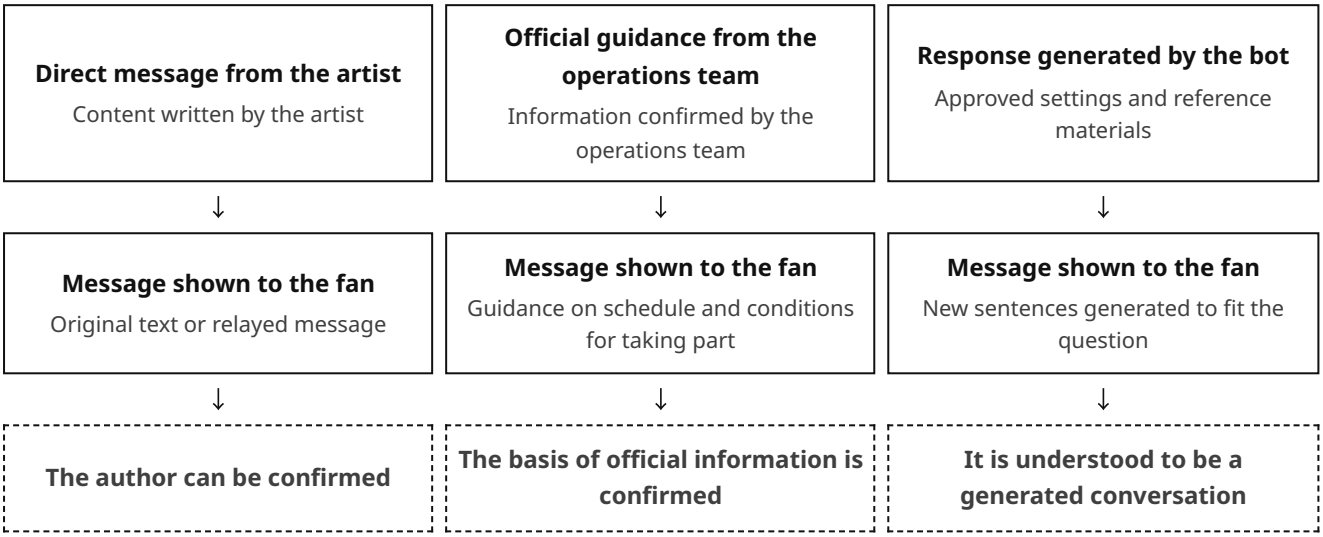

In Korea, Mindlogic presents Blooming Talk, which it developed with A2O Entertainment, as a platform for talking with artist AIs. The developer describes chat that remembers earlier conversations and AI voice and video call features. Overseas, Soul Machines announced in 2023 that it had launched "Digital Mark," a conversational digital twin, together with Mark Tuan. These cases show the form the services took at the time of announcement; they do not prove long-term usage results or current operating status.[11][12]

How closely it resembles the artist is one of the criteria by which fans judge the experience. A 2025 study by researchers at KAIST and Cornell University interviewed 15 fans who had used "AI Private Call," which provides synthesized voice messages of K-pop artists. Participants looked at whether the content of the voice message suited the artist, and accepted its authenticity by checking whether the artist had actually been involved in producing it. Fan communities also influenced how the experience was interpreted. Because this is a small study of a synthesized-voice service, it cannot be generalized to how users respond to all conversational bots.[13]

These results let us think about the artist's participation more concretely. Providing a voice, deciding together on the personality to be expressed, and approving the topics and scope to be used are different ways of participating. What fans want to know may also go beyond simply "Is it exactly like the real person?" Explaining what choices the artist made in creating the experience is what conveys the meaning of the service.

The ability to express a way of speaking also has to be distinguished from the authority to decide on the artist's behalf. A bot may be able to introduce released songs and still have no authority to state unannounced activities as confirmed. Answering a personal question naturally does not mean it knows the real artist's mind. Operators have to define the materials to be used, the personality to be expressed, and the range in which the bot must answer that it does not know.

A message written directly by the artist, guidance confirmed by the operations team, and a response generated by the bot can each be provided in a way that makes the source known. The fact that an artist approved a bot's settings is different from the artist having written an individual response. When this difference is explained, fans can enjoy real messages and generated conversations under different expectations.

Official status describes the relationship of operation and permission. The source of each sentence is indicated separately. The fact that an artist approved a bot's settings is distinguished from the fact of having written an individual response.

Figure 7. Even within the same chat window, the sources of the words differ: for messages inside an official service too, it must be possible to tell who wrote and confirmed them

Within these conditions, an artist's bot can become a creative space. The artist chooses how they want to be expressed and the scope they will allow, and fans make new questions and stories within it. What the bot is to stand in for has to be decided by considering both what the technology makes possible and what the artist chooses.

Chapter 10. What Work Will Managers and Entertainment Companies Hand to Bots?

When a concert venue changes, the information that has to be corrected may not be in just one place. The announcement, the schedule, the entry guidance, and the answers to fan inquiries all have to agree. A work bot can take on the job of checking the changed official information, finding the materials affected, and showing them to the person in charge. People judge and approve what is to be made public and when.

A manager's bot can be set up to gather scattered requests, find scheduling conflicts, and organize what needs to be confirmed. A company's official bot can help fans understand public information and route inquiries to the right person. Schedules under internal review and schedules that may be disclosed to fans have to be handled separately. These work scenes are ideas for use; the actual reduction in workload has to be measured separately.

As a case of supporting concert promotion, Laylo describes its Discovery Agent as a service that recommends concerts based on the artists and regions of interest of fans who have opted in, and connects them to existing ticketing links. In this case the bot's role is closer to promotion that helps people discover concerts. Its operating purpose differs from that of a personal bot to which a fan has entrusted their own judgment.[14]

A fan's personal bot can help with choices based on budget and taste, while a company's bot can provide guidance on the concerts and services it operates. The two roles can cooperate, but their interests are not always the same. Fans can judge the guidance only if they can know the criteria for recommendation and whether it is advertising.

When delegating work, authority can be set separately for the stage of gathering information, the stage of drafting an answer, and the stage of actually sending it outside. It is also important that unfinished requests and approval status carry over even when the person in charge changes. Even if a bot produces drafts quickly, total work may not decrease if people spend more time rechecking facts and fixing errors.

Work efficiency should therefore be examined on the basis of actual processing time rather than the number of answers generated. The time spent on review and rework, how often incorrect guidance occurred, and how many pending requests were missed can be compared before and after introduction. A manager's or company's bot has a role that can be evaluated when the work to be delegated and the person who decides are clearly defined.

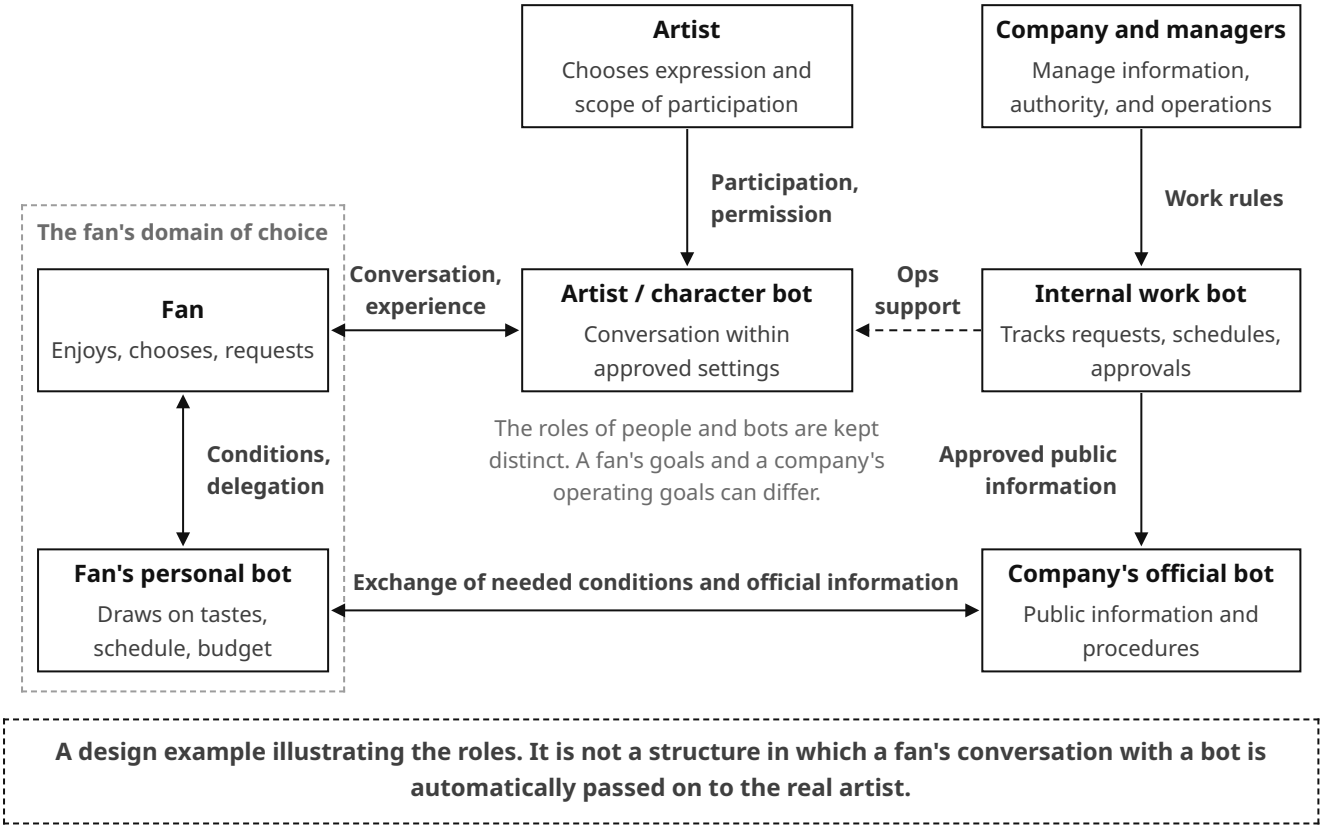

Figure 8. Fans, artists, and companies use different bots: the conversations fans enjoy and the work companies handle are divided by role

Part IV

If Yesterday's Conversation Carries Into Today

Chapter 11. What Should a Bot Remember About a Fan?

When a fan is again recommended a song they said they liked last time, they can feel that their words were remembered. If, because they mentioned that they take public transport to the venue, they receive guidance that fits that condition the next time as well, the need to repeat the same explanation shrinks. This is how memory prepares the next experience.

The memory a bot handles mixes information of different kinds. The setting of a work and published activity information apply to many people in common. A fan's tastes and earlier conversations differ from person to person. Whether an application has been received or is awaiting confirmation is the state of an activity in progress. Keeping these apart reduces the chance that a private conversation is used as if it were official fact, or that an old application is mistaken for a new request.

There are also experiments on how memory is used. A 2026 study in Frontiers in Psychology examined, across six experiments and a total analyzed sample of 2,140, how people respond when an AI says it remembers past information. Conditions that mentioned a memory relevant to the current request were generally rated as more trustworthy than conditions that mentioned a memory that seemed to intrude on privacy. Results compared with conditions that mentioned no memory varied from experiment to experiment.[15]

These results have a clear scope. The experiments did not retrieve user information that had actually been stored for a long time; they mentioned a hypothetical memory within a single conversation. Besides relevance, several other characteristics of the information, such as its sensitivity and usefulness, also differed. It therefore cannot be concluded that long-term memory raises fans' trust or purchases. It does, however, give reason to examine which information is used in which situation.[15]

Applied to fan services, we can evaluate differently a case where a seat recommendation draws on seat preferences the fan shared before and a case where a personal worry is brought up while recommending merchandise. This is a design example thought through on the basis of the research. Beyond the accuracy of memory, what matters is whether the fan agrees to, and can expect, that information being used in this conversation.

It is also necessary to show fans what is being remembered and let them correct or delete what is wrong. But the mere existence of an editing function does not make every use of memory appropriate. Permission to store information and permission to use it for recommendations with a different purpose also have to be handled as distinct.

Figure 9. A hand choosing a photo from a keepsake drawer: the fan decides what to keep and what to erase. Like the sealed envelope, not every record has to be opened to the bot

Memory has to carry time with it. Music someone loved last year cannot be assumed to be their favorite now. Nor should a feeling mentioned in passing during a conversation be taken as a lasting disposition. When a bot checks a past preference again, the fan can correct the context to fit who they are now.

Technically, memory can be implemented by referring back to conversation logs, summaries, or separately stored materials. Not every conversation has to be fed into the training of the model itself. As Bot Accounts discusses, managing the necessary memories so that they are linked to activities and can be changed becomes the condition for continued use.[8]

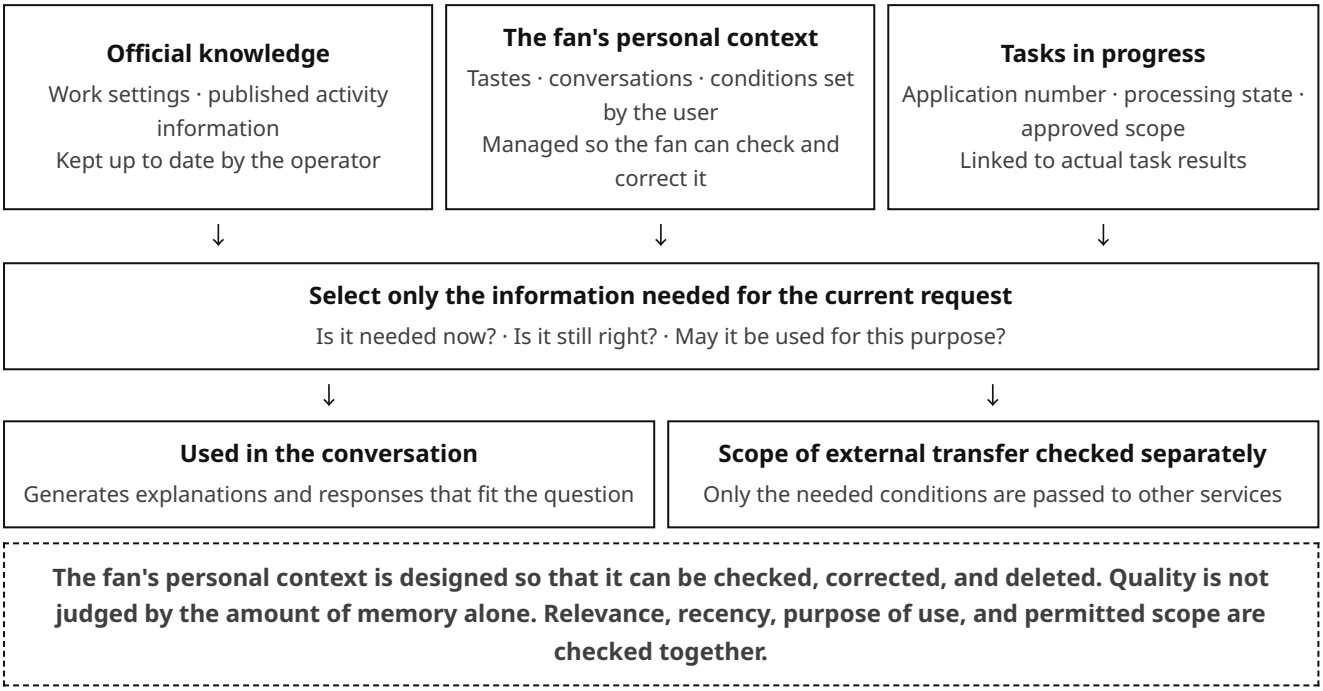

Figure 10. Memory is managed by kind and by context of use: using stored information in the current conversation and passing it to an outside party are judged separately

Chapter 12. Who Remembers Me, the Bot or the Artist?

Let us return to the opening scene. After the concert the fan shared their impressions, and the bot replied remembering the song they had said they liked a few days earlier. The joy the fan felt in that moment is a real experience. But what produced that experience needs an accurate explanation.

The fact that a bot drew on a fan's conversation does not allow us to say that the real artist read it or remembers it. A personalized response and the personal attention of the artist are different facts. A fan can know this difference and still like talking with the bot, and a design that respects that choice is possible.

Here the relationships between fan and artist, fan and bot, and fan and operating company exist together. The one the fan loves may be the artist, but what is producing the response now is the bot, and the party keeping the records may be the company. Even if the artist took part in creating the bot, it cannot be inferred that they have read every individual fan's conversation. The scope of participation and the scope of what records are passed on have to be explained separately.

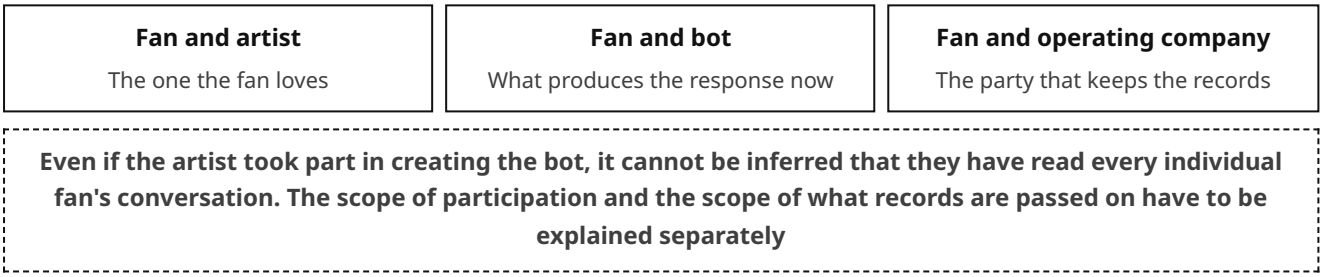

Figure 11. Three relationships present together in a single conversation

In the AI Private Call study, the way fans checked whether the artist had been involved in production prompts us to think about this distinction. The authenticity a fan feels can include the judgment that the artist was involved in creating the experience. But confirming involvement in production and confirming that the artist personally sent the present response are separate things.[13]

A study published as a CHI extended abstract in 2026 interviewed 18 fans who had interacted deeply with idol-type AIs. The researchers interpreted that attachment to the existing idol influences conversations with the AI, and that experiences with the AI can also feed back into perceptions of the real idol. As a qualitative study of a particular group, it cannot be generalized to the responses of all fans or to business results. It does, however, support the argument that the two experiences are hard to treat only separately.[16]

Operators can communicate these differences through sender labels on the conversation screen and explanations of messages. If there is a feature that passes something on to the real artist, fans can be allowed to choose what is passed on and confirm who receives it. Approaches that lead fans to assume every conversation is shared, or that word things as if the artist had read what was never passed on, should be avoided.

Respecting a fan's feelings is different from leaving those feelings to be confused with fact. When fans can understand how a response was produced and the extent to which memory was used, they can take in the time they spend with a bot in their own way.

Chapter 13. When the App Changes, Where Does the Time Spent with a Bot Go?

Imagine switching from an app you have used for a long time and finding that in the new service you have to explain everything again. Your favorite songs, your record of concerts attended, and the plans you put together remain only in the old app. A fan may feel they have lost the context built up over that time. The longer a service is used, the more it matters what is kept and what can be carried forward.

The Future Structure of Bot Accounts raises the question of whether the context built up between a person and a bot can be carried forward even when the model or service changes. From this perspective, continuity does not mean the same program running forever. It is a design question of deciding what is inherited and what has to be confirmed anew.[9]

The issue also shows up in real shutdown notices. Tencent's agent platform Yuanqi (元器) announced in an October 2026 notice that the service would end on November 9, and gave guidance on exporting agent settings, workflows, and conversation records and on migrating to other services. It set January 9, 2027 as the deadline for exporting data after the shutdown. Although not a case of a fan-specific service, it shows a real situation in which the end of a bot's operation and the preservation of records have to be dealt with together.[17]

At this point, the preservation of records, the transfer of functions, and the continuity of experience can be looked at separately. If you receive the conversation files, the records can be kept. If the new service accepts the settings and connection functions, some functions can be moved as well. But whether the experience is maintained, in which earlier memories are interpreted in the same way and responses come in a similar voice, has to be checked separately. A notice that export is supported does not by itself guarantee all of this.

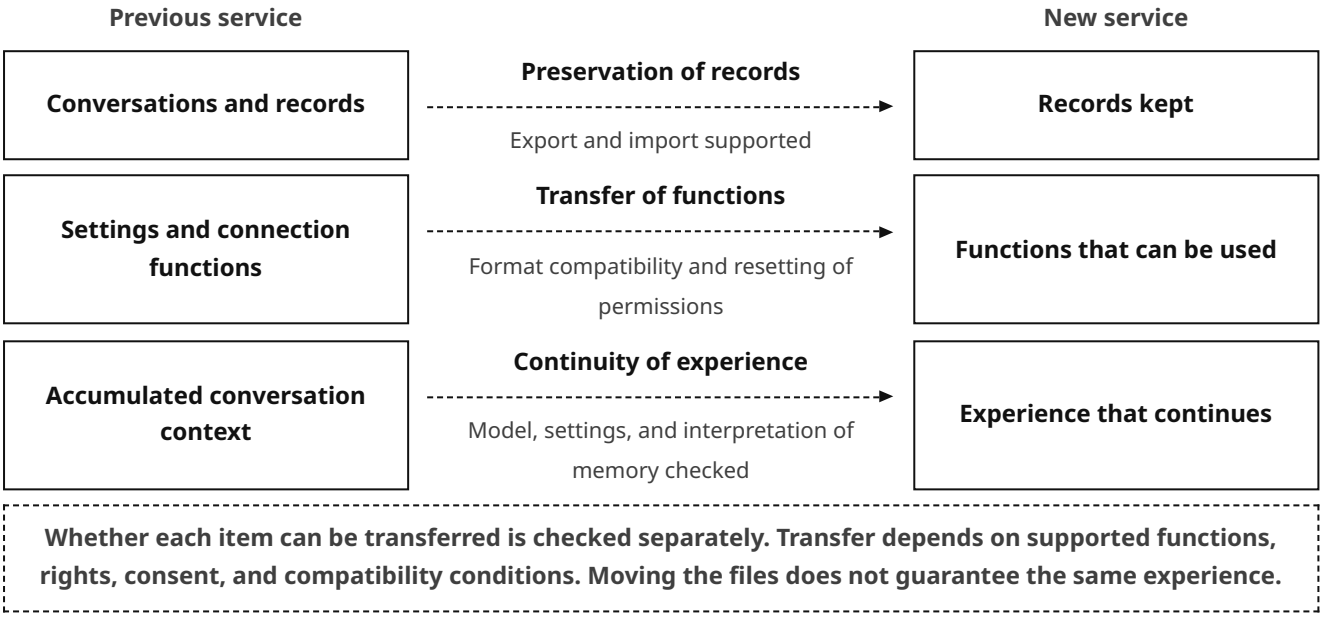

Figure 12. When changing services, three things are checked separately: copying records, moving functions, and continuing the conversation experience are different things

The account that identifies the bot, the model that processes the conversation, and the app the user sees are also different things. Changing the model under the same account can change how it responds. Even with the same model, a different operator, different settings, and different reference materials make it a different bot. Keeping the same name does not mean the same experience continues.

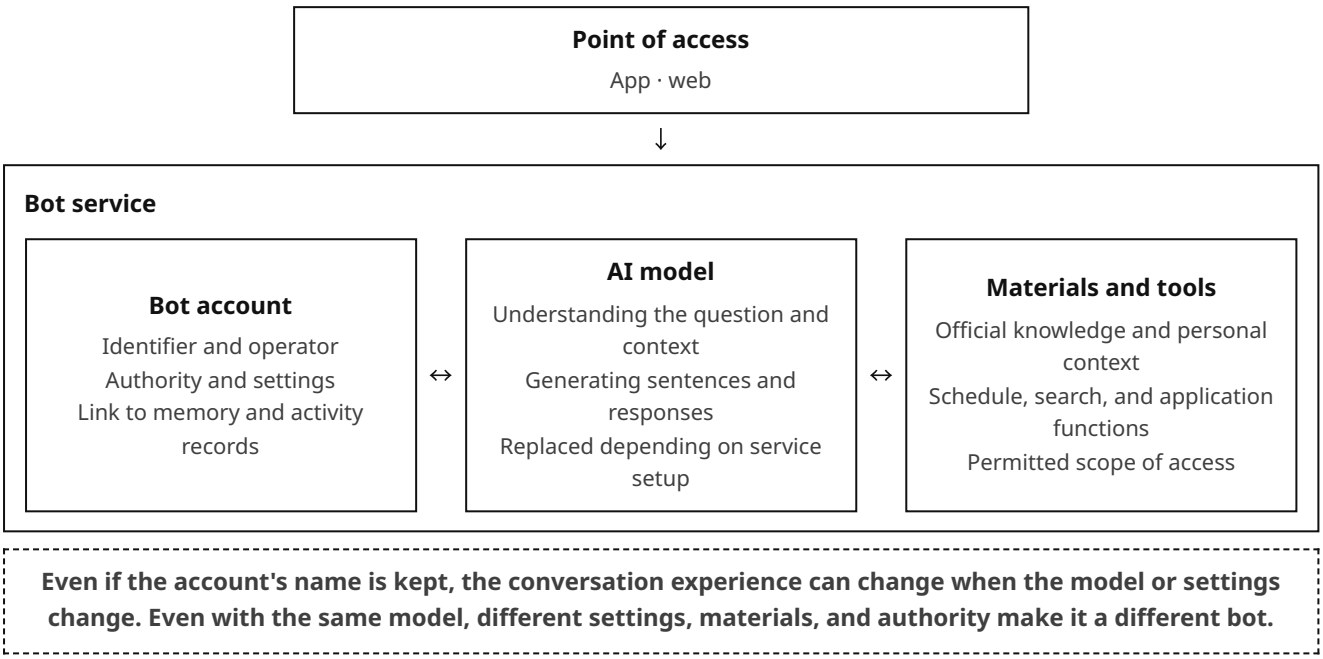

Figure 13. The app, the bot account, and the AI model play different roles: the app is the point of access, the account links the bot's information, and the model supports understanding and generation

There are differences in what information can be moved, too. The tastes and activity records a fan entered, the character settings a company provided, and materials that include third parties' rights cannot all be treated under the same conditions. It has to be decided what information can be exported and what the new service can accept. Designing so that individuals control their own information and claiming that legal ownership of all materials belongs to the individual are different assertions.

When a service ends, it should offer a chance to review the records and allow applications and payments in progress to be settled. It should also explain which records will be deleted when, and what may change after migration. An operation that respects the time fans have built up includes procedures for the end as well as explanations at the start.

Part V

When My Bot Contacts Someone Else's Bot

Chapter 14. Do Bots Need Contact Addresses Too?

When we contact a person, we know that a name alone is not enough. Several people can have the same name, so we check a phone number or account address. A similar problem arises as bots multiply. From the name "Concert Guide Bot" alone, it is hard to know which bot it is and which company operates it.

Here a bot's name, identifier, and contact address play different roles. The name is the label people use to recognize and call it. The identifier is the basis for telling a particular bot apart within a system, and the address points to where requests are sent. Even when they look like one thing on the screen, they serve different management purposes. Knowing a contact address does not by itself mean that the other party is trustworthy or that anything may be done with it.[8][9]

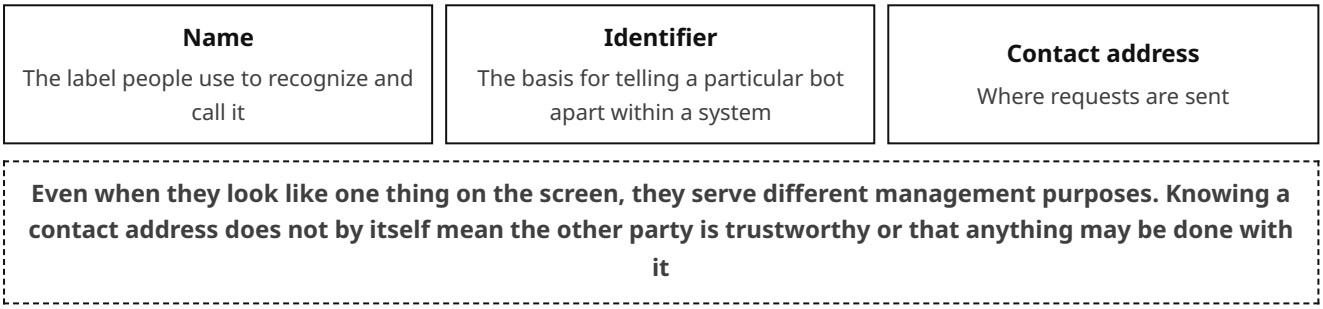

Figure 14. A bot's name, identifier, and contact address

For example, for a fan's bot to check official concert information, it has to know which service to connect to. It also has to confirm whether that connection is a route the company has announced and what functions the other side provides. Conversely, the company needs to confirm for which user, and within what scope, the requesting bot is working.

The phrase "giving a bot an address" does not necessarily mean creating a new number shaped like a phone number. The other party can also be found by a web address or a method of identification within a service. What matters is a structure that makes it possible to reach a particular bot, confirm who operates it and what functions it provides, and deliver the necessary request.

From this perspective, a bot account has a broader role than a name attached to a chat window. It becomes the unit of management that links who operates the bot, what authority it has, and what records it carries forward. There is no basis for interpreting the granting of an account to mean that a bot gains human-like consciousness or personhood. In this report, the account is a concept for explaining continued use and work.[8]

Chapter 15. What Do the Fan's Bot and the Company's Bot Exchange?

Suppose a fan asks their bot, "Find a concert I can go to next month." The personal bot looks at the schedule and travel conditions the fan has allowed, and checks concert dates and venues with the official service. Where necessary, it also asks about membership conditions or the application deadline. The company's bot passes on the information and procedures it is able to disclose.

In this process, there is no need for all of the fan's conversation records to be handed to the company. It can be designed so that only the conditions needed for the request, such as the dates the fan can attend or the region they have chosen, are passed on. Confirming that a condition is met can also be kept separate from disclosing the private circumstances behind it. For example, where it is enough to confirm only that a date is free, there is no need to pass on why another appointment on that day was canceled.

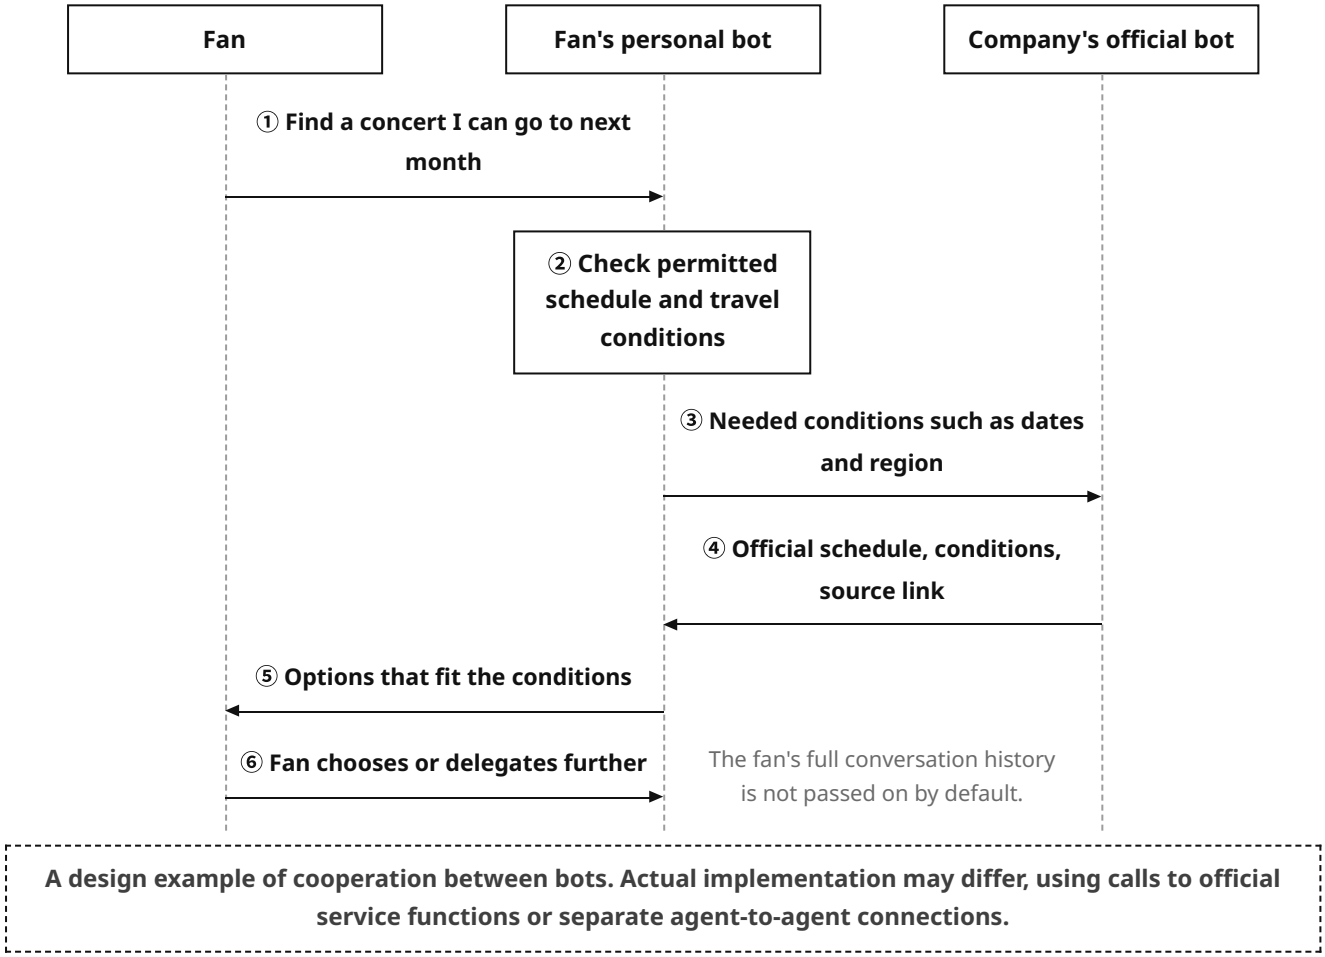

Figure 15. My bot passes only the needed conditions to the official bot: a communication flow using a fan's concert search request as the example

In this report, bot communication is the way software with roles exchanges the necessary information and requests, processing states, and results. It does not have to be conversation in sentences, the way people talk. Data in a fixed format, such as a date or an application number, can also be exchanged. What matters is that both sides understand the meaning of the information passed on and the processing state in the same way.

Figure 16. Cards passing between two envelopes: the fan's personal bot and the company's official bot exchange only what is needed, such as schedules and concert information. The closed notebook is the personal record that is not handed over

There are several ways of actually connecting. One bot may call a ticketing service's functions directly, or it may hand the request to a separate bot. A2A is one example of a protocol for confirming an agent's capabilities and exchanging tasks and results. It is designed so that agents cooperate without disclosing all of their internal implementation. But using such a protocol does not by itself create actual authority to do the work or an agreement between companies.[18]

In September 2026, Ticketmaster announced a connection that lets Meta's personal agent Muse explore concert and ticket information. It was described as a structure in which the user looks at concerts and seat and price information that fit their interests, and completes the purchase on Ticketmaster. It is a case of personal AI connecting with an official service, but it should not be read more broadly as a case of independent artist bots negotiating with each other or completing purchases automatically.[19]

The existence of a connection protocol, a connection with an official service, and working cooperation between bots that represent different users thus have to be explained separately. The A2A documentation deals with the technical structure for cooperation, and Ticketmaster's announcement shows a connection in which a personal agent explores official information. Whether fans' and companies' bots actually exchange authority and complete work has to be confirmed through separate operating cases. The scene in this chapter of a fan's bot and a company's bot cooperating is a sketch that explains that possibility.

The value of bot communication can be evaluated by whether the fan's request comes back as accurate information and a processed result. As intermediate steps increase, it must be possible to confirm who passed on what and what is being waited for. Distinguishing the connection itself from work that has actually been completed is the starting point.

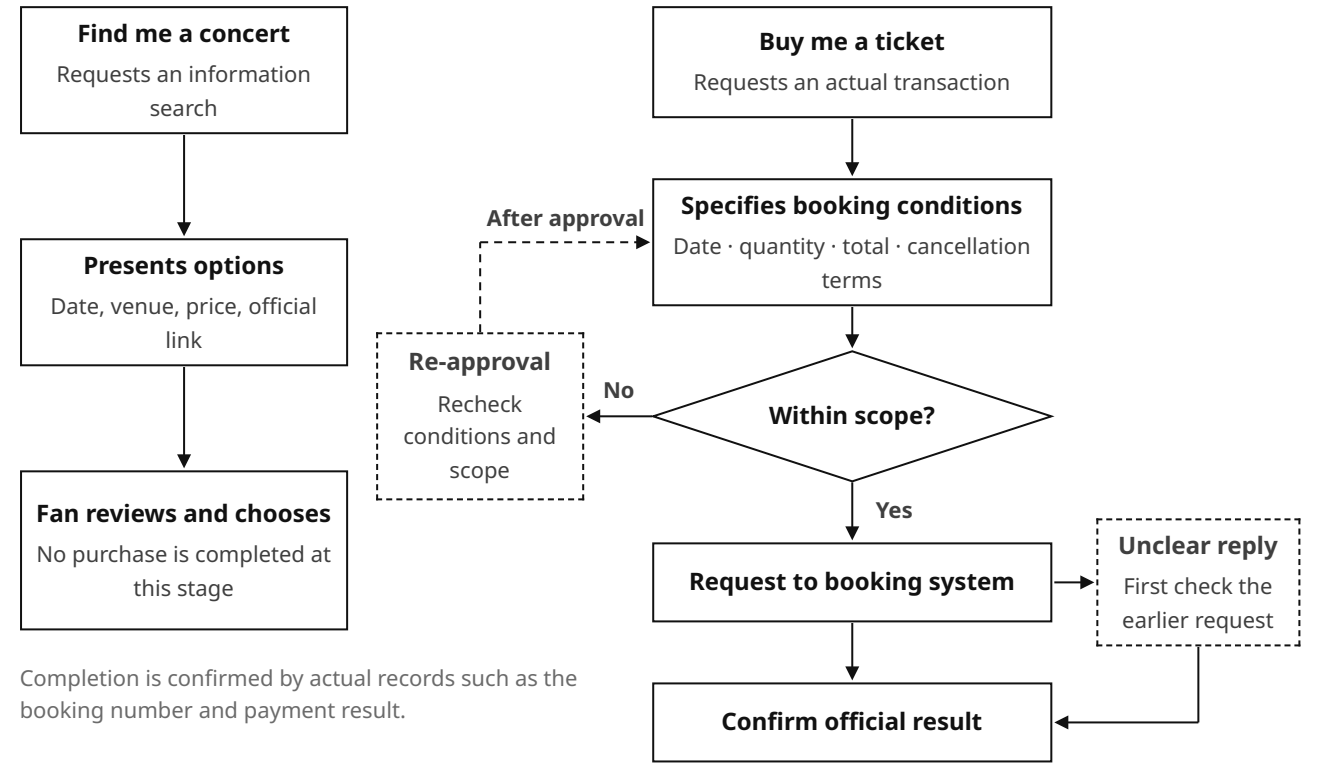

Chapter 16. How Is Getting a Concert Recommendation Different from Delegating the Booking?

Asking for concert information to be found and asking for a ticket to be bought are different requests. The former is a matter of obtaining the material needed to make a choice; the latter is a matter of carrying out a real transaction in which money, seats, and cancellation terms are at stake. Even when the bot answers in the same chat window, the authority the fan entrusts to it is different.

If the booking is delegated, the conditions need to be set out specifically. The result changes depending on which date, how many tickets, the maximum total including fees, and whether another date may be chosen when no seats are available. The phrase "just get me good seats" contains many choices that can be interpreted differently. The bot has to confirm what is needed for the decision and act within the permitted scope.

Within conditions set in advance, the bot can be allowed to proceed, and when the conditions are exceeded, it can be made to seek approval again. The fan must be able to cancel the delegated task or change its scope. It should also be made known that withdrawing a delegation and canceling a purchase that has already been completed are separate procedures, because a completed transaction is subject to the terms of the service concerned.

Nor should completion be judged merely because the bot says, "I've booked it." It has to be confirmed that a booking number and payment result actually exist in the ticketing system. If the response is cut off after a payment request, the operation should first check the status of the existing request rather than assume it failed and pay again right away. This is why "received," "in progress," and "completed" are kept distinct.[8]

A design example of booking automation. When the permitted scope is exceeded, further approval is obtained; when the response is unclear, the status of the existing request is checked first.

Figure 17. Getting a recommendation and delegating a booking are different: a real transaction needs specific conditions, authority to execute, and confirmation of the result in the external system

The principles for agent identity management that NIST proposed in October 2026 also address the link to the person or organization that delegated the task, limited authority, revocation of authority, and human review. These are early design principles, not mandatory rules specific to entertainment. They can nonetheless serve as a reference in that a bot's actions have to be tied to the intent of the person who delegated them.[20]

The booking scene in this chapter is a hypothetical to explain what delegation means. The scope of automation that can actually be offered depends on the ticketing service's functions and operating policies and on the authority granted. The bot's role begins with making those conditions something the fan can understand and choose.

Part VI

How Far Has the Market Come?

Chapter 17. Which Services Are Building Today's Market Between Them?

Looking at the official materials checked in November 2026, the functions related to always-on agents are being implemented across several kinds of services. Services that let individuals hand off recurring tasks, platforms that carry on a company's business processes, underlying technologies that provide memory and execution environments, and services that connect fan activity with purchasing are all appearing together. This report compares representative official documents and announcements to explain how they relate. It is not a list surveying every market participant, nor a ranking by market share.

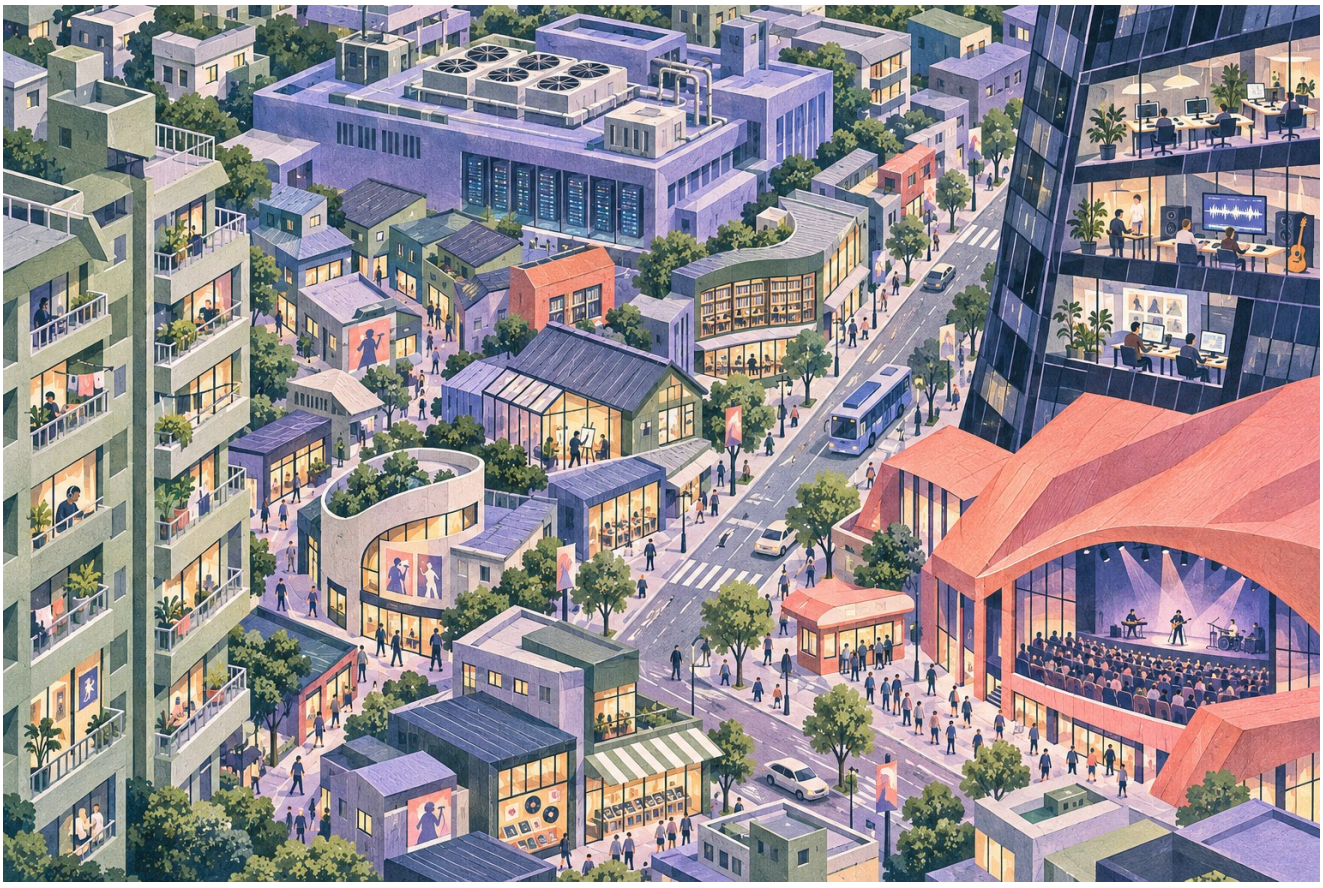

Figure 18. A city of connected buildings: the homes stand for personal services, the offices for enterprise services, the server facility for the technology base, and the concert hall for entertainment services. It is not a map of where real companies sit or of their market share

First, there are the services individuals use in daily life. In June 2026 ChatGPT announced an expansion of scheduled tasks, which provide recurring runs and checks for changes, and in August it introduced tasks triggered by events in connected apps. Pulse, which had earlier shown research on proactive personalization, was described in the June announcement as being retired, with its functions moved into scheduled tasks. It is therefore not appropriate to keep listing Pulse as a separate current service when describing today's ecosystem. What has to be checked is which function is provided where, not whether a product name has been kept.[21]

Anthropic's Claude Cowork can likewise schedule recurring research, report writing, and similar work. The help documentation checked explains that scheduled tasks run in a remote environment and so work even when the computer is asleep or the desktop app is closed. It does specify, however, that some local tasks created in the past keep their existing way of running. This case shows that the statement "it runs even after the conversation ends" has to come together with where it runs and under what conditions. The range of supported tools and connected accounts also has to be checked service by service.[22]

OpenClaw shows an approach in which users set up an execution environment on their own device or server and connect several messaging channels to the agent. The functions that handle scheduled runs and external notifications operate within that environment. Because users can choose the operating environment themselves, the responsibility for maintaining the server, configuring connections, and managing updates and access rights has to be considered as well. An approach in which the service provider manages execution and one in which the user manages the execution environment exist side by side.[7]

On enterprise platforms, continuity of work is tied to how the organization operates. Microsoft introduced, in Copilot Studio, agent accounts, memory that carries business context forward, and execution functions that respond to time or events. In its official description of November 4, 2026, the feature that uses an agent's own approved credentials and limited permissions is marked as being in private preview under the Frontier program. It should not be described as a function every company already uses in general. What deserves attention is the direction: carrying work forward through the roles and permissions of the organization, beyond whether the one employee who delegated the task is logged in.[23]

Salesforce's documentation on Agentforce describes a setup in which an agent is run when customer or business data changes. It looks up data and starts the next step, including human review and approval where necessary. Such enterprise functions are a foundation entertainment companies can refer to when handling inquiries, changes to announcements, and pending requests. An implementation presented in another industry cannot, however, be taken directly as a result for fandom operations.[1]

Beneath these are the foundation services that make it possible to run agents. AWS's Amazon Bedrock AgentCore provides, as components, an execution environment, memory, tool connections, identity and access permissions, and the ability to check action logs. Google Cloud's Agent Platform Memory Bank describes a function for storing the necessary personal context across multiple conversation sessions and using it again. These are not products that complete a particular artist's voice or a fan experience; they are technologies that can be used to build and operate such services. The existence of foundation functions has to be read as distinct from the existence of a finished fan service.[24][25] A company can subscribe to a finished bot, or it can combine these foundation technologies to build its own service. An agent business can therefore concentrate on the materials, connections, and operations of a particular kind of work without developing a general-purpose model itself. This is a business interpretation based on how the foundation services are composed.

Common protocols are also becoming important for connecting different services. MCP is a protocol that aims to standardize how AI applications connect to external data and tools. A2A is a protocol designed for independent agent systems to confirm capabilities and exchange tasks and results. The two protocols deal with different aspects of connection. Using them does not mean one can access any company's service or freely move every bot's memory. Actual data provision, authentication, usage rights, and agreement on what the work means have to be aligned separately by the participants.[26][18]

In Korea, the connection with existing services stands out. In July 2026 NAVER explained a direction in which its AI Tab uses search, shopping, local, and content information to carry exploration through to purchase and reservation. The announcement can be read as a case of the agent's role expanding within everyday domestic services. But a statement that search and execution are connected is not enough to conclude that it maintains a user's goal over the long term and handles every task automatically.[27]

In October 2026 Kakao introduced Kanana Space and Kanvas. Kanana Space was presented as an interface for requesting messages, schedules, search, and more within KakaoTalk, and Kanvas as a direction for building and running agents on a personal PC by connecting tools and skills. According to the official announcement, a closed beta of Kanana Space was planned from December, and a small closed beta of Kanvas within the year at the earliest. Expansion into ordering, reservations, and money transfers is likewise set apart as a future plan. As of this survey, it is accurate to present these as announced concepts scheduled for testing.[28]

On fan platforms, functions that connect conversation with official content are taking concrete shape. In its October 27, 2026 update, Weverse announced that it had widened the search scope of Weverse AI to include artist posts and added a response-language setting. In its March 2026 overview of Berriz's operations, Kakao Entertainment introduced AI personas based on characters in works and an AI comment report that summarizes fan reactions. These functions show the forms of AI already in use within the fan experience. This material alone does not allow the conclusion that each platform provides an always-on agent that acts autonomously on a fan's behalf over the long term.[29][30]

Meanwhile, connections through which a fan's personal agent finds outside entertainment services can also be confirmed. In September 2026 Ticketmaster announced a setup in which it connects with Muse, Meta's personal agent service, to present concerts and ticket information that fit the user's interests, with the final purchase made on Ticketmaster. At the time of the announcement, it applied to an English-language service for users in the United States and Canada. This case shows that a route has appeared for fans to discover concerts outside the official fan app. It should not be interpreted as a case in which the agent independently completes the purchase.[19]

Area	Representative cases	Confirmed role and status
Personal services	ChatGPT scheduled tasks Claude Cowork	Provide recurring runs and use of connected tools. Scope and run conditions differ by service.[21][22]
Self-operated environment	OpenClaw	Connects messaging channels and automation tasks on the user's own device or server.[7]
Enterprise work platforms	Copilot Studio Agentforce	Connect business events with memory. Copilot's agent-specific credential feature is in private preview.[1][23]
Execution and memory foundation	AWS AgentCore Google Memory Bank	Provide foundation functions such as execution, memory, and access management for developers to assemble.[24][25]
Connection protocols	MCP A2A	Deal with connecting external tools and exchanging tasks between agents. They do not automatically guarantee access to services or compatibility.[26][18]
Everyday services in Korea	NAVER AI Tab Kakao's agent plans	NAVER provides a connection between exploration and execution. Kanana Space and Kanvas are at the stage of announcement and planned closed testing.[27][28]
Fan experience and activity	Weverse AI · Berriz Muse and Ticketmaster	Provide official content search, character conversation, and concert discovery. The scope of each function has to be distinguished.[29][30][19]

Table 2. Roles taken on in today's agent ecosystem

Seen this way, competition in the ecosystem is not explained by models that generate good answers alone. It also takes the point of contact where users keep handing off work, the services that provide the needed information, the tools that carry out tasks, and the operating environment that maintains context and authority. One company may provide several of these areas, or the technologies and content of several companies may be combined within a single experience. Which will become the general winner is hard to judge from the current material alone.

Publicly available functions and actual business results are also separate questions. Even when scheduled execution is confirmed in official documentation, that does not tell us the rate at which it runs without failure over a long period, or the profitability of an entertainment business. Fan demand, information-provision agreements, operating costs, and processing quality have to be checked together. What the current material supports is the fact that the functions making up continuous execution and connection are being provided at several layers; it is not a claim that a single market in which every service is already seamlessly connected has been completed.

Chapter 18. What Numbers Show the Market's Growth?

Large figures labeled "AI market size" or "AI agent market forecast" cannot be used as they are for the market size of always-on bots in entertainment. The surveys behind them mix customer support, software development, internal work automation, and many kinds of agents. Where the target of the business has not been defined, it is more useful to look at which uses are expanding and what spending and paid demand can be confirmed than at market size.

In August, McKinsey published a survey of 1,719 respondents in 97 countries conducted from May 4 to June 8, 2026. Forty percent of respondents at large companies with annual revenue above 1 billion dollars said they were scaling AI agents in at least one business function; among smaller companies the share was 22 percent. About 20 percent of all respondents said their use was constrained by AI operating costs. This shows that wider adoption and cost management are proceeding together, but it is not a result that surveyed only entertainment companies or always-on services.[31]

A survey Gartner published in September 2026 also shows the gap between spread and results. In the survey, conducted from January to April 2026 among 1,303 respondents at companies with 2025 annual revenue of 50 million dollars or more, 22 percent of organizations had scaled AI across multiple business units or adopted an AI-first approach. This figure covers AI in general, and its questions and sample differ from the McKinsey agent survey above. The two numbers must not be set side by side and calculated as if they were the same adoption rate for one market.[32]

In the fan market, the operating scale of an actual paid service can be looked at separately. DEARU's earnings release for the third quarter of 2026 gave an average of 1.97 million subscriptions for the quarter. This is one company's case showing that a market exists in which fans pay for messaging and content experiences. But the number of subscriptions is not the same as the number of unique users, and it does not mean the number of paying users of an AI service or the willingness of fans as a whole to pay for AI.[33]

Source and period	Confirmed indicator	What the indicator does not directly mean
McKinsey Survey, May–June 2026	40% of respondents at large companies said they were scaling AI agents[31]	The penetration rate among all companies, the adoption rate in entertainment, or the share of continuous-execution services
Gartner Survey, January–April 2026	22% had scaled AI across multiple business units or adopted an AI-first approach[32]	The result of the same question as the row above, or the adoption rate of AI agents alone
DEARU Announced for Q3 2026	Average of 1.97 million subscriptions[33]	1.97 million unique fans, or the number of paid subscriptions to AI bots

Table 3. What to keep distinct when reading market indicators

The judgments that can be drawn from these figures are limited but useful. Companies are moving beyond the stage of testing agents into scaling them, and verifying cost and operating results is becoming important. Paid demand already exists in fan services, but willingness to pay extra for new AI functions has to be confirmed separately. A number produced by multiplying an existing fan platform's user count by an arbitrary conversion rate and price is a business assumption, not a verified market size.

Chapter 19. What Is the Market Starting to Pay For?

Looking at the basis for billing gives a more concrete understanding of the value each provider sells. Character conversation and fan communication services can offer access and a continuing experience as a subscription. Bots for work can be billed by employee account or by volume processed. Agents that work continuously incur costs for the number of runs, the use of external tools, and even the handling of results. A single billing method does not, however, correspond to only one type of technology.

Intercom's Fin is a case that shows billing by type of outcome. In its official guidance of September 2026, a resolution and certain procedure handoffs are listed at 0.99 dollars each. A resolution includes not only cases where the user confirms they were satisfied with the answer but also cases where the user ends the conversation without asking for further help after the last answer. So when reading the label "pricing per outcome," the definition of the outcome has to be checked as well. Prices are not the same for every outcome type or for voice services, and platform seat costs have to be considered separately depending on how the service is set up.[34]

The cost structure of development foundation services is different again. AWS describes usage-based billing for the components of AgentCore, such as execution, memory, and tool connections. A company operating a continuous-execution service can incur, beyond model usage fees, costs for the execution environment, data lookups, connections to external services, record management, the time people spend on review, and error handling. It is not a structure in which profit rises simply because functions are run more.[24]

The revenue structures that can be considered in entertainment also differ depending on who the buyer is. If fans find value in keeping track of their own schedule and cutting preparation time, a personal service subscription can be considered. If a company can handle repeated inquiries or announcement changes more accurately, a fee for an operations tool is possible. For conversation experiences that use official characters or artist IP, the use of rights and revenue sharing become a separate issue. These are candidate business models, not results in which actual willingness to pay or profitability has been confirmed.

When the fan is the buyer	When the company is the buyer
If they find value in keeping track of their own schedule and cutting preparation time Personal service subscription	If it can handle repeated inquiries or announcement changes more accurately Operations tool fee

For conversation experiences that use official characters or artist IP, the use of rights and revenue sharing become a separate issue. These are candidate business models, not results in which actual willingness to pay or profitability has been confirmed

Figure 19. Candidate revenue structures that differ by buyer

To enter the market, there has to be a reason to pay extra compared with free notifications, calendars, and existing fan apps. If the service merely forwards announcements, it may offer little differentiation. If it can sort out changes across several official sources, narrow the options to the conditions the fan has set, and carry forward requests that have not been handled, it can offer a different kind of value. Evaluating this requires checking not only the number of conversations but also the completion rate of delegated tasks, missed and duplicate notifications, satisfaction with results, and whether users return and keep paying.

Part VII

How Will the Entertainment Industry Change When Bots Arrive?

Chapter 20. What Should Entertainment Connect in This Ecosystem?

Let us think again about a fan's day. In the morning the fan asks their agent to summarize this week's official news. During the day they work, and in the evening they come back and check concert news that fits their schedule. On the weekend they talk about a work with a character bot, and after the concert they record their impressions. This scene is an example to explain possible uses. It does not mean that a single service currently provides this whole process.

In this flow, the fan's personal agent carries forward the conditions the fan has set. The company's official service provides confirmed activity information and participation procedures. The bot connected to the artist or character creates a conversation experience within the approved range of expression. The internal operations agent manages announcement changes and pending requests. These roles may sit inside the same app or be divided among different services. What matters is making clear what each role knows and what it can do.

Here, the fact that internal information has been finalized is different from the fact that it may be disclosed externally. Even if the internal operations agent refers to an unannounced schedule, it can be excluded from the information provided to the fan's personal agent. When an external bot makes a request through the official interface, only the necessary information is provided, such as the published schedule, participation conditions, the link to the original, and the time of the last update. Such a connection does not require exchanging the artist's private life or the whole of a fan's personal conversations.

Read against this ecosystem, the questions an entertainment company has to consider extend beyond building the screen of its own bot. It also matters whether the personal agents fans already use can accurately find the company's official information, whether they can tell apart the procedures that can be applied for and the actions that are not possible, and whether they can confirm the new status when information changes. The connection between Muse and Ticketmaster is one case that shows this direction. The conclusion is not that every entertainment company must open up in the same way, but that it provides grounds for considering external touchpoints as an option for business and operations.[19]

Connecting official information does not necessarily require building another AI agent on the other side. For some tasks, the existing way of connecting services, which provides schedules and participation conditions in a set format, is enough. Agent-to-agent communication can be considered when independent agents need to coordinate requests and results over several steps. What comes first is whether a request can be understood, authority confirmed, and a result returned, rather than which technology name has been adopted.[18][26]

The business roles also become concrete here. The artist and the company decide the names, voices, and story worlds that can be used, and the information that is public. Technology providers can supply the agent's execution, memory, tool connections, and status checks. Fan platforms can take charge of the point of use and the content, and ticketing and merchandise services of the actual transactions and their results. Dividing what the company implements itself from where it uses external functions makes it easier to explain what the costs are for and who manages quality. This is a division of roles drawn from the cases surveyed, not an established industry standard or revenue-sharing model.

Party	Role it can take on
Artist and company	Decide the names, voices, and story worlds that can be used, and the information that is public
Technology providers	Supply the agent's execution, memory, tool connections, and status checks
Fan platforms	Take charge of the point of use and the content
Ticketing and merchandise services	Take charge of the actual transactions and their results

Table 4. Division of business roles drawn from the cases surveyed

The results of always-on operation can be evaluated by whether the work was properly carried forward rather than by how many days the service was left running. That means looking at whether necessary changes were missed, whether the same notifications and requests were repeated, whether changes to conditions and requests to stop were reflected, and whether the cause and next step were communicated when something failed. Costs, too, have to include not only model usage fees but also the execution environment, information connections, human review, and error handling. Profitability can be judged only by looking at these costs together with actual usage, payment, and retention data.

What the always-on agent adds to entertainment is a way of operating that can carry a fan's interest forward to the next point in time. A record remains of when the fan delegated what and how that task is progressing, and the company can respond to the request through approved information and functions. Continuity over time is added to the conversation experience, memory, and bot communication. Only when this continuity respects the fan's choices and the scope of the artist's participation can it develop into a service people have reason to use for a long time.

Chapter 21. How Can We Know That This Bot Is Official?

Suppose you come across a bot with a familiar face and voice. The conversation is natural, and it knows a lot about the artist's activities. These features alone make it hard to judge that it is a service the artist or company has authorized. The degree of resemblance and the actual authority to operate have to be checked separately.

To explain official status, it has to be clear who operates the bot, which names and materials it may use, and what experience it has been approved to provide. The route that leads from the artist's or company's official channels, and the operating notice, can be a starting point. The authenticity a fan feels and a verifiable relationship of authorization are connected, but neither one alone proves the other.

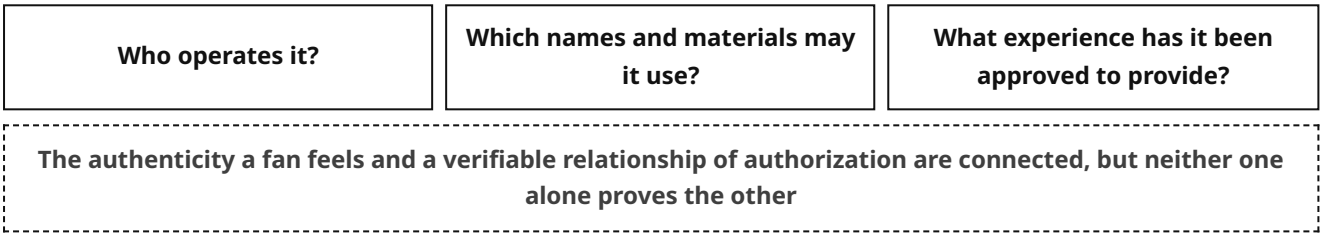

Figure 20. What has to be made clear when explaining official status

There is also a case from an adjacent field in which authorization has been built into operating procedures. On November 9, 2026, the global advertising agency Ogilvy announced ECHO, an advertising production platform. Built in partnership with CAA (Creative Artists Agency), a major U.S. entertainment and sports agency, it is a service that uses celebrities' likenesses and voices in AI advertising production on the premise of their consent. According to the official description, it is designed so that the system checks the conditions for using a celebrity's digital likeness, voice, and so on, and each output is released only after final approval from the artist's side. It also presented a label indicating approval and the fact of AI reproduction.[35]

ECHO is not a fan conversation bot, and the company's announcement is not material that independently verifies long-term results. Even so, its way of operating, which links the materials that can be used, the outputs, and the person who approves them, is worth referring to. If it is difficult to pre-approve every response of a real-time bot, then the topics and expressions to allow, the activities to restrict, and the procedure for stopping when a problem arises have to be designed concretely.

Even within an official bot, the kinds of statements can differ. A function that delivers messages written by the artist, a function that explains announcements finalized by the operations team, and a function that generates new conversation according to its settings can exist side by side. The label "official service" explains the operating relationship. It does not go so far as to mean that the artist personally wrote every sentence or approved it as a real promise.

For example, when an official character bot says "Let's go on a trip together next time," that may be part of a fictional story. If it is taken as a promise of a real fan event, expectations change. It has to be possible to tell which context a generated line belongs to and whether an event that can actually be applied for exists.

Official status also includes renewal and termination. When activity information changes or an operating contract ends, the scope of approval and the public information have to be revised. It has to be decided which names and voices can be used until when, and who will reflect the changed conditions. Trust in an official bot is maintained through verifiable authorization and operations that keep within its scope.

Chapter 22. Who Should Set Things Right When a Bot Says or Promises Something Wrong?

Imagine that a bot gave the wrong entry time and a fan arrived late to a concert. The fan needs someone from whom they can receive accurate guidance, to whom they can explain their situation, and of whom they can request the necessary action. A sentence acknowledging the error does not by itself resolve the problem.

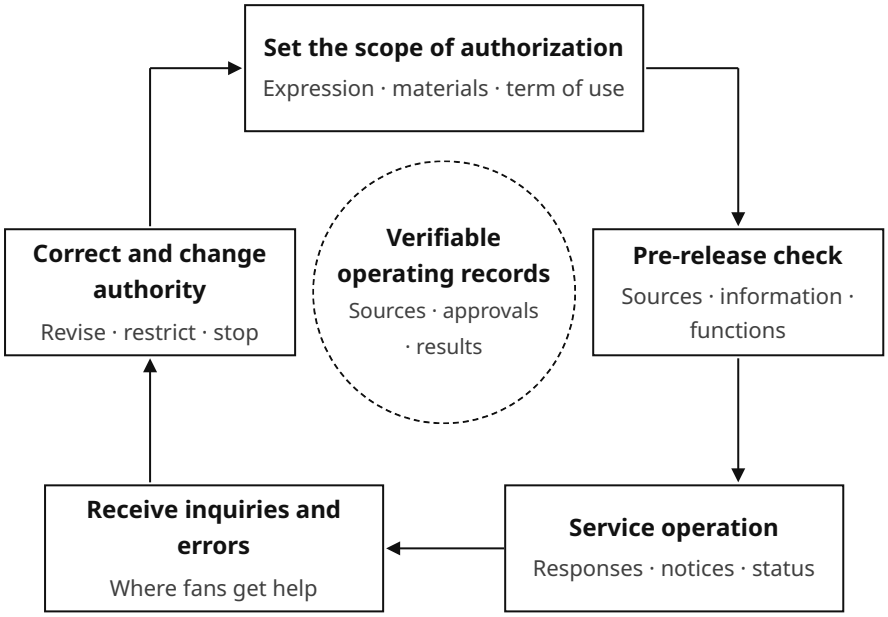

The cause of an error can lie in several places. The original announcement may have changed without being reflected, or the bot may have misunderstood the question. A problem may also have arisen in interpreting information received from another service or in a staff member's approval process. The cause can be narrowed down only if it is possible to check which materials and processing steps were involved.

This is why the roles of the developer that built the bot, the company that actually operates the service, the staff member who provided the information, and the user who requested the action have to be distinguished. The developer can fix problems in how the bot behaves, and the operating company can provide fans with a correction notice and a point of contact. Legal liability in an individual case has to be judged according to the facts, the contracts, and the applicable law, but who receives and coordinates the matter at the service level can be decided in advance.

Records are kept so that this can be explained. They make it possible to check which version of an announcement was referenced, who approved what, and what request was actually sent. Necessary work records and records of personal conversations can be kept separate, with the scope of retention and access rights defined for each. Storing every private conversation indefinitely is not a requirement of responsible operation.

When responses outside the scope of the artist's authorization keep recurring, a procedure is also needed for stopping the function concerned and revising its settings. It can be decided whether the whole service has to be suspended or only a particular voice or topic can be restricted. Blocking responses that would be produced in the future also has to be distinguished from correcting or dealing with outputs that have already been made public. The specific way of handling this has to take both prior agreements and the actual state of distribution into account.

The handoff to a person is also part of the service. If a problem cannot be handled by the bot, the necessary details can be organized and passed to the staff member so that the fan does not have to repeat the same explanation. Even then, it has to be possible to know what information is being passed on and to whom. The fan has to be able to check whether the matter is being handled, whether further confirmation is needed, and through which channel they can get an answer.

Who takes on what

Artist and rights holders
Choose participation and scope of authorization

Company and managers
Update information and respond to fan inquiries

Developer
Fix technical errors and behavior

Fan
Choose · request · raise issues

An example of service operation roles. The point of contact, the person responsible for corrections, and the authority to stop a function are decided in advance.

Figure 21. Trust in an official bot is maintained in operation: it does not end with authorization and release, but feeds inquiries, errors, and changes in authority back into operation

Chapter 23. What More Can Fans Gain Through Bots?

The value that returns to fans can take many forms. They can enjoy a story in a new way by talking with characters from a work, and they can easily find official information that is scattered about. They can also organize their own impressions or pick up creative work they had been doing. Cutting down the tedious checking needed to prepare for a concert can be valuable too.

How much of this value has been created has to be looked at in line with the bot's role. For a character bot, what matters may be fun, consistency of the setting, and whether fans can add their own ideas. For a guide bot, one can look at the accuracy of information and whether problems were solved. For an operations bot, one can review how the results of processing and the burden of human checking have changed.

Bot's role	What to look at
Character bot	Fun, consistency of the setting, and whether fans can add their own ideas
Guide bot	Accuracy of information and whether problems were solved
Operations bot	How the results of processing and the burden of human checking have changed

Table 5. Criteria for examining value according to the bot's role

Nor can a good experience be inferred merely from the fact that time spent has increased. A 2025 study by researchers at MIT and others examined chatbot use among 981 people over four weeks. No significant effects were found for the assigned conversation modes and topic conditions, but poorer psychosocial outcomes were observed among participants who voluntarily used the chatbot more. Because usage was not randomly assigned, it cannot be concluded that heavy use caused those outcomes. Nor is it a study of bots made for fans.[36]

With this material in mind, a service's results can also be examined by criteria other than time spent and number of messages. This means checking whether fans completed the activity they wanted, whether they are satisfied with the conversation experience, and whether they understand the scope of the artist's actual participation. A use in which the fan received convenient guidance and ended the conversation quickly can also be a success. If the same error was repeated, the experience has to be improved even if the conversation was long.

The parts fans want to do themselves also have to remain. Choosing what to say, waiting for a concert, and sharing impressions with other fans have meaning in the process itself. Even when a bot polishes the writing or finds information, the fan has to be able to remain the one who expresses and chooses. Nor can the number of automatically generated comments or messages be read as equal to a fan's affection.

For entertainment companies, this creates a task of preparing creation and operation together. They have to decide what story world the conversation will let fans experience, how far the artist will participate and authorize, and how official information will be maintained. If there is a function that handles tasks fans delegate, connections to actual services, approval, and handling of inquiries are needed as well. Roles have to be designed to include the operation that follows connecting a model.

The business potential has to be verified through this experience. It has to be checked whether fans actually want it and have reason to use it again, whether they are willing to pay, and whether the effort needed for operation can be sustained. Launch cases show that services have appeared, and user studies offer clues for understanding the experience. Neither kind of material guarantees that the same revenue or retention will occur for every artist and fandom.

The claims to be verified can also be divided concretely. Subscription effects have to be examined through actual payments and retention, and savings in work through time that includes review and reprocessing. Connecting work between bots requires records showing that authority was confirmed and the request was handled to the end. For the transfer of memory, whether the file was successfully moved and whether the user experience continued have to be evaluated separately.

Claim to verify	How to check
Subscription effects	Actual payments and retention
Savings in work	Time including review and reprocessing
Connecting work between bots	Records showing that authority was confirmed and the request was handled to the end
Transfer of memory	Evaluate separately whether the file was successfully moved and whether the user experience continued

Table 6. Claims to verify and how to check them

When applying this to individual entertainment companies, SM included, one also has to start from what kind of fan experience they want to create. The combination of services differs according to the roles the artist and company allow, the activities fans want to do themselves, and the problems to be solved in current operations. Only after these choices have been made concrete can it be judged which of character conversation, a fan's personal assistant, an official information service, and internal operations bots should be connected.

Chapter 24. What Business Opportunities Remain for Entertainment Companies?

In today's ecosystem, natural conversation and a certain level of automation can be built simply by using general-purpose AI services. It therefore has to be clear what an entertainment business offers beyond that. The accuracy of official information, the scope within which artists and characters can be used, the connection to actual work, and a sender label fans can understand can be the elements that make the difference. These elements are not secured merely by changing the model.

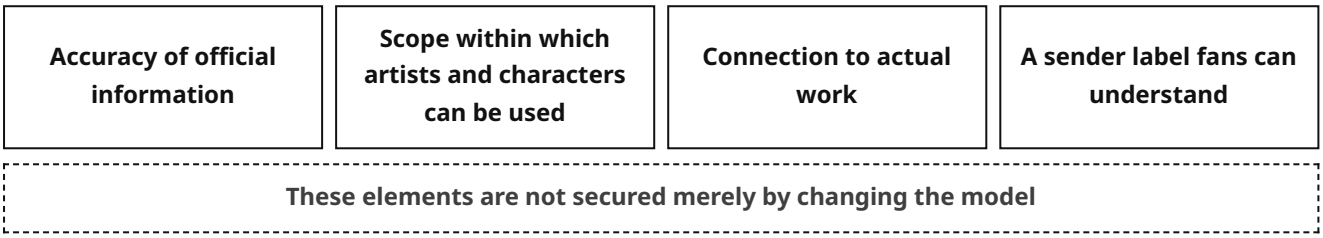

Figure 22. What an entertainment business can offer beyond that

If a concept to propose to SM is being considered, three roles can first be thought of separately. The fan's personal agent carries work forward on the basis of the fan's schedule, budget, and interests. The bot connected to the artist or character creates a conversation experience within the approved range of expression. The operations agent of the company and managers handles official information, pending requests, and approval procedures. These roles could be offered in a single app, but who is working for whom has to be kept distinct.

The fan's personal agent and the company's sales goals are not always aligned. The fan may want to spend less, while the company may want to increase participation in concerts and merchandise. If advertising or partnership terms influence recommendations, the fan has to be able to understand those criteria. The ability to hold on to fans for a long time or make them buy more often cannot be evaluated as the same thing as the ability to handle the fan's work well.

The first description of the business can also be written around these roles and results. For example, "a service that checks changes in official announcements, compares them with the conditions the fan has set, and tells the fan what preparation is needed and how things are progressing" allows the necessary materials and evaluation methods to be defined fairly concretely. For managers, one could consider "a service that finds the scope of impact of a changed schedule, drafts the revisions, and goes on managing approvals and results." Sentences like these are examples of business concepts and do not describe anything SM has currently adopted.

Where the aim is to offer conversational content, separate questions are needed. It has to be examined whether the experience is one fans would enjoy, whether the artist's actual messages can be told apart from generated conversation, and whether expression stays within the scope of the approved IP. The efficiency of an operations tool and the enjoyment of character conversation are different kinds of value, so they are hard to explain with a single performance figure.

The business value of an always-on agent has to be confirmed in how far its ability to carry delegated work forward improves fans' activities and the company's operations.

Conclusion

What Relationship Will We Build Between Fans and Artists?

Let us return to the concert hall where we began. A fan conveys how they feel about a favorite song, and the bot responds to that story. The fan can put their impressions into writing or create a new story. If their own agent checks information on the next concert and helps them prepare, the experience of conversation leads on to later activity.

Within it are the closeness felt toward the artist, the pleasure of interpreting a work, and the meaning of sharing time with other fans. The bot's role has to be defined within this variety of experience. The artist's participation and authorization set the scope of what can be offered, and the purpose for which memory is used and how far it is passed on have to be something fans can understand and choose.

In this report, an entertainment bot means software that has a role connected to fans, artists, characters, and organizations, creates experiences, carries the necessary context forward, and performs permitted activities. Bot communication is the way those roles exchange information and requests, processing status and results. Not every bot needs to have every function.

The always-on agent adds operation that maintains the delegated work and its conditions and carries tasks forward at the right time. Today, personal services, enterprise work platforms, the foundation technologies for execution and memory, and fan platforms and transaction services each provide part of that function. Connecting them requires deciding together on the official information, the rights of use, and who will operate.

When fans remain the ones who express and choose, artists decide the scope of their participation, and companies and managers can explain the handling process, this concept becomes a concrete service. Its value has to be confirmed in what fans have come to enjoy more and be able to do.

Figure 23. Into the concert hall, phone put away and ticket in hand: the preparation that technology helped with has to lead to an experience the fan sees, hears, and enjoys in person

Glossary

Term	Explanation
Bot	Software that responds to input or carries out activities according to a defined role. This report mainly deals with AI-based bots used in conversation and fan activity.
AI model	A technology that provides part of a bot's capabilities, such as understanding and generating language. Even with the same model, bots differ according to the materials, tools, and operating rules connected to them.
Agent	Software configured to use tools and carry out multi-step tasks toward a delegated goal. In this report, the word is used when describing the side of a bot that performs activities.
Persona	The tone, personality, and role a bot is set to express in conversation. It is not the same concept as the whole inner life of a real person.
Bot account	A unit of management that links a bot's identity with its operator, memory, authority, activity records, and so on. It is distinct from a single name or password.
Context	The background needed to understand the current conversation and task. It can include earlier conversations, preferences, task conditions, and processing status.
Delegation and authority	Delegation is the relationship of entrusting a certain range of work, and authority is the range that has been permitted for actual access or execution. Making a request does not automatically create every authority.
Bot communication	The way bots exchange the information, requests, processing status, and results they need. It can take place not only in sentences people read but also in data in a set format.
IP	A term meaning intellectual property. In this report it is used to describe content with rights attached, such as works and characters. The scope within which names or settings can be used has to be checked against the individual rights and contracts.

Parasocial relationship	The continuing sense of closeness and bond felt toward a person in the media. It does not mean that a fan's feelings are false, nor is it a diagnosis that their real-life relationships are lacking.
Synthetic voice	A voice generated or reproduced using technology. The fact that it resembles a real person's voice does not by itself mean that the person said or approved the sentence in question.
Official status and authenticity	Official status refers to verifiable relationships such as the operator and the scope of authorization. Authenticity is a judgment about how fans perceive the connection with, and participation of, the artist. The two concepts are related but do not automatically prove each other.
Conversation-centered bot	A term of comparison that groups together services which take a user's question or specific request and provide answers and work. It does not mean that all existing bots have the same functions.
Always-on agent	An agent that maintains the delegated goal, the necessary context, authority, and task status, and starts or continues work when prompted by time or events. This is the working definition of this report and does not mean uninterrupted execution or unlimited autonomous action.
Trigger	The time, event, or condition that starts a task. It can be the posting of a new announcement, a set check time, a staff member's approval, and so on.
Execution environment	The computer or cloud environment in which an agent's program actually runs. Whether work continues after the screen is closed depends on this environment and the service settings.
MCP	An open protocol that deals with how AI applications connect to external data and tools. Supporting the connection protocol is distinct from being granted actual access rights.
A2A	An open protocol designed for independent agent systems to exchange capabilities, task status, and results. It does not guarantee the free transfer of all memory or authority.

References and Sources

Materials checked as of November 11, 2026. Descriptions of services are based on the functions stated at the time of announcement or on official pages. Company announcements were used as grounds for launches and descriptions of functions, and were kept distinct from independent verification of profitability. The samples and scope of application of research findings are indicated in the text and in each source. The added section on the agent ecosystem was written mainly from official documents checked in November 2026, and interpretations of how things work and how roles are divided, together with examples of use, were kept distinct from actual results of adoption. The scope of services and prices may differ by country, plan, and update. Survey figures follow each organization's sample and definitions and were not added together as figures for different markets.
